1 Introduction

This work mainly focuses on the concept of ℓ^2 -Betti numbers. These are invariants defined for manifolds with group action introduced by Atiyah in [7]. Originally Atiyah asked if ℓ^2 -Betti numbers can be irrational. Since then many statements about whether or not some numbers can be ℓ^2 -Betti numbers arising from specific groups are called the Atiyah conjecture.

One of these conjectures, namely that every ℓ^2 -Betti number is always rational is often called the strong Atiyah conjecture. Over the time this conjecture has been disproven several times. For example Łukasz Grabowski showed in [1] that all real numbers are ℓ^2 -Betti numbers arising from some group. To this end he introduced a method of computing ℓ^2 -Betti numbers by creating an appropriate Turing machine. This work is mainly a reformulation of the work he has done in [1] with the exception of section 5.1 where we will use his methodology to show that every rational number arises from the lamplighter group.

In section 2 we give a short introduction to the theory of ℓ^2 -Betti numbers which we do mainly to fix notation. At the end of that section we will show that an ℓ^2 -Betti number arising from a group can be computed just from elements of the respective group ring and without using manifolds or CW-complexes, a fact which we will make heavy use of later on.

In section 3 we introduce the notion of a Turing dynamical system, which is an extension of Turing machines. In addition we will show how a Turing machine can be transformed into a Turing dynamical system.

Section 4 then focuses mainly on proving the method used in [1]. This will be done by introducing groupoids and generating a groupoid for a Turing dynamical system.

In section 5 we use this theory to first show that every rational number arises from the lamplighter group L and then construct a Turing machine which proves that a certain irrational number is an ℓ^2 -Betti number of L^3 as is also done in [1].

2 ℓ^2 -Betti numbers

At first we will give a short introduction into the theory of ℓ^2 -Betti numbers. For a wider approach see [2]. We will assume some basic knowledge about cellular homology and the associated Betti numbers. For more information on this topic see e.g. [3]. As an alternative a reader not familiar with these topics may just accept the results of 2.3.3 and study the definitions given in section 2.1.

In this whole chapter G is always a discrete countable group with multiplication \odot_G .

2.1 Von Neumann Dimension

At first let us begin with some basic definitions.

Definition 2.1.1. The *group ring* RG over a ring R is the free module over G with the additional multiplication

$$\sum_{h \in H} \alpha_h h \odot_{RG} \sum_{k \in K} \beta_k k = \sum_{h \in H} \sum_{k \in K} \alpha_h \beta_k h \odot_G k$$

with $\alpha_h, \beta_k \in R$ and $H, K \in G$ finite subsets.

If R is a field then RG is an algebra and in particular a vector space with dimension $|G|$ if G is finite. We will often see the group ring $\mathbb{C}G$. If G is infinite then $\mathbb{C}G$ is an infinite dimensional vector space with scalar product. In this case $\mathbb{C}G$ is not a Hilbert space. Therefore we will introduce the space $\ell^2(G)$ which is in fact the Hilbert space completion of $\mathbb{C}G$.

Definition 2.1.2. $\ell^2(G)$ is the Hilbert space consisting of formal sums $\sum_{g \in G} \lambda_g g$ such that $\lambda_g \in \mathbb{C}$ and $\sum_{g \in G} |\lambda_g|^2 < \infty$. The multiplication is defined as in 2.1.1 and the scalar product is defined by

$$\langle \sum_{g \in G} \alpha_g g, \sum_{h \in G} \beta_h h \rangle := \sum_{k \in G} \alpha_k \overline{\beta_k}.$$

Remark 2.1.3. If G is a set instead of a group we can also define a Hilbert space $\ell^2(G)$. Of course we do not have a multiplication in this case.

We now want to define a dimension for spaces embedded in $\ell^2(G)$. In most cases the normal vector space dimension of these spaces will be infinite and therefore not useful. We will instead use the von Neumann dimension which requires some preliminary work.

Definition 2.1.4. The *group von Neumann algebra* $\mathcal{N}(G)$ is defined as the algebra of (left-) G -equivariant bounded operators from $\ell^2(G)$ to $\ell^2(G)$ where G acts on $\ell^2(G)$ by left multiplication.

We will denote the bounded operators of a Hilbert space H_1 by $\mathcal{B}(H_1)$. If G acts on a Hilbert Space H_2 the subspace of G -equivariant elements of H_2 will be called H_2^G . Therefore we can also define the group von Neumann algebra by $\mathcal{N}(G) := \mathcal{B}(\ell^2(G))^G$.

Definition 2.1.5. Let $e_G \in G$ be the unit element of G . Then

$$\mathrm{tr}_{\mathcal{N}(G)}: \mathcal{N}(G) \rightarrow \mathbb{C}, A \mapsto \langle A(e_G), e_G \rangle$$

is called the *von Neumann trace* on $\mathcal{N}(G)$.

Remark 2.1.6. *Right multiplication with an element of the group ring $\mathbb{C}G$ is a G -equivariant operator on $\ell^2(G)$ and therefore has a well defined von Neumann trace. Note that left multiplication with an element of $\mathbb{C}G$ is not G -equivariant if G is not abelian.*

Definition 2.1.7. A Hilbert $\mathcal{N}(G)$ -module is a Hilbert space H with a linear isometric G -action such that there exists an isometric linear G -embedding from H to $\ell^2(G)^n$ for some $n \in \mathbb{N}$.

Definition 2.1.8. Let H be a Hilbert $\mathcal{N}(G)$ -module and let

- $\iota: H \rightarrow \ell^2(G)^n$ be a corresponding embedding
- $\mathrm{pr}_{\iota(H)}: \ell^2(G)^n \rightarrow H$ be a corresponding G -equivariant projection
- $\iota_i: \ell^2(G) \rightarrow \ell^2(G)^n, y \mapsto (0, \dots, y \dots 0)$ be the inclusion of the i -th $\ell^2(G)$
- $\mathrm{pr}_i: \ell^2(G)^n \rightarrow \ell^2(G), (x_1, \dots, x_n) \mapsto x_i$ be the corresponding projection.

Then

$$\mathrm{tr}_{\mathcal{N}(G)}: \mathcal{B}(H)^G \rightarrow \mathbb{C}, A \mapsto \sum_{i=1}^n \mathrm{tr}_{\mathcal{N}(G)}(\mathrm{pr}_i \circ \iota \circ A \circ \mathrm{pr}_{\iota(H)} \circ \iota_i)$$

is also called the *von Neumann trace* on H .

One can show that the trace is independent of the chosen embedding and therefore well-defined.

Remark 2.1.9. *A different way to understand the definition of the von Neumann trace on Hilbert $\mathcal{N}(G)$ -modules is the following: A Hilbert $\mathcal{N}(G)$ -module H can always be seen as a G -equivariant subspace of some $\ell^2(G)^n$. A map $A \in \mathcal{B}(H)^G$ can then be expanded to a map on $\ell^2(G)^n$ by first projecting onto H and then using A . In addition a map on $\ell^2(G)^n$ can be seen as a matrix of maps on $\ell^2(G)$.*

Taking the von Neumann trace of A then simply means expanding A to a map on $\ell^2(G)^n$ and then adding up the von Neumann trace of the diagonal entries of the matrix of this map.

Definition 2.1.10. Let H be a Hilbert $\mathcal{N}(G)$ -module. We define the *von Neumann dimension* of H as

$$\dim_{\mathcal{N}(G)}(H) = \mathrm{tr}_{\mathcal{N}(G)}(\mathrm{id}_H).$$

Remark 2.1.11. Let $H \subset \ell^2(G)$ be a subset which is closed under G and $\text{pr}_H: \ell^2(G) \rightarrow H$ a G -equivariant projection. Then

$$\dim_{\mathcal{N}(G)}(H) = \text{tr}_{\mathcal{N}(G)}(\text{pr}_H) = \langle \text{pr}_H(e_G), e_G \rangle.$$

Remark 2.1.12. The von Neumann dimension is additive, i.e. if H_1 and H_2 are two Hilbert $\mathcal{N}(G)$ -modules, then

$$\dim_{\mathcal{N}(G)}(H_1 \oplus H_2) = \dim_{\mathcal{N}(G)}(H_1) + \dim_{\mathcal{N}(G)}(H_2)$$

holds.

2.2 ℓ^2 -Betti numbers of G -CW-complexes

One can now define the ℓ^2 -Betti numbers of CW-complexes in a very similar way as for cellular homology. But first we have to define a group action on CW-complexes.

Definition 2.2.1. Let X be a CW-complex and $\rho: G \rightarrow \text{Homeo}(X)$ an action of G on X by homeomorphism such that for every open cell $E \subset X$ and every $g \in G$ it holds that $\rho(g)(E)$ is again an open cell and $\rho(g)|_E = \text{id}_E$ if $\rho(g)(E) \cap E \neq \emptyset$. Then ρ is called a *cellular action*.

Definition 2.2.2. A G -CW-complex is a CW-complex together with a cellular G -action.

Definition 2.2.3. The *orbit* of an n -cell in a G -CW-complex is called a G -equivariant n -cell.

Definition 2.2.4. Let X be a G -CW complex. X is called

- *proper* if all stabilizer groups are finite,
- *free* if all stabilizer groups are trivial,
- *finite type* if for every $n \in \mathbb{N}_0$ it has only finitely many G -equivariant n -cells.

Remark 2.2.5. One can show that the chain complex of a G -CW complex X is a chain complex $C_*(X)$ of left $\mathbb{Z}G$ -modules, i.e. each $C_n(X)$ is a left $\mathbb{Z}G$ -module and the differentials are $\mathbb{Z}G$ -module-homomorphisms.

Definition 2.2.6. The ℓ^2 -chain complex of a G -CW complex X is

$$C_*^{(2)}(X) = \ell^2(G) \otimes_{\mathbb{Z}G} C_*(X).$$

Definition 2.2.7. Let X be a proper, finite type G -CW complex and $C_*^{(2)}(X)$ the corresponding ℓ^2 -chain complex with its differential $d_*^{(2)}$. Then

$$H_n^{(2)}(X) := \ker(d_n^{(2)}) / \overline{\text{im}(d_{n+1}^{(2)})}$$

is called the n -th ℓ^2 -homology and

$$b_n^{(2)}(X) = \dim_{\mathcal{N}(G)} H_n^{(2)}(X)$$

the n -th ℓ^2 -Betti number.

Remark 2.2.8. *One can show that for a proper, finite type G -CW complex X , the n -th ℓ^2 -homology $H_n^{(2)}(X)$ is a Hilbert $\mathcal{N}(G)$ -module and therefore the ℓ^2 -Betti number is in fact well-defined.*

2.3 ℓ^2 -Betti numbers arising from a group

We will now show that it is sufficient for our purpose to calculate the von Neumann trace of the kernel of elements of the group ring without mentioning CW-complexes.

Remark 2.3.1. *A matrix $A \in \mathbb{C}G^{n \times m}$ can be seen as an operator from $\ell^2(G)^n \rightarrow \ell^2(G)^m$ via $x \mapsto x^\top \cdot A$. We will refer to this map also by A . This operator is G -equivariant. Be aware that if G is not abelian this is not the same operator as $A^\top x$, which in this case is not G -equivariant.*

Lemma 2.3.2. *For a matrix $A \in \mathbb{C}G^{n \times m}$ the kernel $\ker(A)$ is a Hilbert $\mathcal{N}(G)$ -module and therefore has a well-defined von Neumann-dimension.*

Proof. Of course $\ker(A)$ is a subspace of $\ell^2(G)^n$. We can use $\text{id}|_{\ker(A)}$ as embedding. It remains to show that $\ker(A)$ is closed under the natural G -action on $\ell^2(G)^n$. So let $x \in \ker(A)$ be an element in the kernel and $g \in G$ be an element of the group. It now holds that

$$(g \cdot x)^\top \cdot A = g \cdot (x^\top A) = g \cdot 0 = 0$$

because the action is linear. □

Theorem 2.3.3. *Let $x \in \mathbb{R}$ and G be a discrete, countable, finitely generated group. The following are equivalent:*

- i) There exists a cocompact free finite type G -CW-complex X and an integer $n \in \mathbb{N}$ such that $b_n^{(2)}(X) = x$.*
- ii) There exists a matrix $A \in \mathbb{Q}G^{n \times n}$ for an integer $n \in \mathbb{N}$ such that $\dim_{\mathcal{N}(G)}(\ker(A)) = x$.*

Proof. “ $i) \Rightarrow ii)$ ” Let X be a cocompact free finite type G -CW-complex and $l \in \mathbb{N}$ such that $b_l^{(2)}(X) = x$. We define

$$\Delta_l^{(2)} = d_l^{(2)*} d_l^{(2)} + d_{l+1}^{(2)} d_{l+1}^{(2)*},$$

which is a map from $C_l^{(2)}(X)$ to $C_l^{(2)}(X)$. The differential can be written as a matrix $A' \in \mathbb{Z}G^{n \times n}$ for some $n \in \mathbb{N}$ and therefore $\Delta_n^{(2)}$ also lies in $\mathbb{Z}G^{n \times n}$. In addition one can show that $\ker(\Delta_n^{(2)}) = H_n^{(2)}$ holds.

“ $ii) \Rightarrow i)$ ” Let $n \in \mathbb{N}$ and $A \in \mathbb{Q}G^{n \times n}$. Because $k \cdot A$ has the same kernel as A for every $k \in \mathbb{Z}$ we can assume that $A \in \mathbb{Z}G^{n \times n}$. The corresponding map will be also called A . We will construct a G -CW-complex X with $d_3^{(2)} = A$ and $d_4^{(2)}$ trivial. Therefore $H_3^{(2)}(X) = \ker(A)$ and $i)$ follows.

First we can see that a graph can always be seen as a CW-complex with the edges as 1-cells and the vertices as 0-cells. Let $g_1 \dots g_m$ be generators of G and let Y be the corresponding Cayley graph of G which has a natural cellular free G -action and is therefore a free, finite type G -CW-complex. In addition it has exactly one G -equivariant 0-cell and m G -equivariant 1-cells and no other cells. We then glue n many 2-cells on each 0-cell, i.e. we attach them via the attaching map which sends all of S^1 to a single point. For an example of this G -CW-complex with $G = \mathbb{Z}$ and $n = 2$ see Figure 1.

Figure 1: An example of the G -CW-complex before gluing in the 3-cells for $G = \mathbb{Z}$ and $n = 2$.

We now glue in n many G -equivariant 3-cells in such a way that A corresponds to $d_3^{(2)}$. We describe the procedure for the first row. The procedure for the other rows is done analogously. Let $A_{ij} = \sum_{g \in G} z_{(g,i,j)} g \in \mathbb{Z}G$ denote the entry in the i -th row and the j -th column of A . We fix one 0-cell and call it e and we call the corresponding 2-cells $e_1 \dots e_n$. We glue in $G \times D^3$ where each element $h \times D^3$ is glued $z_{(g,1,j)}$ many times to $hg \cdot e_j$ for each $g \in G$ and $j \in \{1, \dots, n\}$. We then see that $d_3^{(2)}$ maps the vector

$$\left(\sum_{g \in G} \lambda_g g, 0, \dots, 0 \right) \in (\ell^2 G)^n$$

to

$$\left(\sum_{g \in G} \sum_{h \in H} \lambda_g z_{(h,1,1)} gh, \dots, \sum_{g \in G} \sum_{h \in H} \lambda_g z_{(h,1,n)} gh \right) \in (\ell^2 G)^n.$$

Figure 2 shows how one 3-cell $e \times D^3$ is glued on the above G -CW-complex for the first row of $A = \begin{pmatrix} 1 \cdot 0 + 1 \cdot 2 & 1 \cdot 1 \\ 0 & 0 \end{pmatrix}$. The 3-cell is glued once into each of the gray 2-cells.

Figure 2: The above example after gluing in one 3-cell.

We then repeat this for every row of A and get that $d_3^{(2)} = A$. The resulting G -CW-complex X is still free, finite type and because X/G is finite X is cocompact. \square

Remark 2.3.4. *One can show that 2.3.3 also holds if G is not finitely generated.*

Definition 2.3.5. We say that a number $x \in \mathbb{R}$ arises from a discrete countable group G if it fulfills one (and therefore both) of the conditions of 2.3.3.

The statement of 2.3.3 will be implicitly used in many points of this work. In fact we will never construct a G -CW-complex and instead construct an element of a group ring $\mathbb{Q}(G)$ of G which kernel has the desired von Neumann dimension.

Lemma 2.3.6. *If $x \in \mathbb{R}$ and $y \in \mathbb{R}$ both arise from a discrete, countable group G , then so does $x + y$.*

Proof. Let $A \in \mathbb{Q}G^{n \times n}$ and $B \in \mathbb{Q}G^{m \times m}$ for some $n, m \in \mathbb{N}$ such that

$$\dim_{\mathcal{N}(G)}(\ker(A)) = x$$

and

$$\dim_{\mathcal{N}(G)}(\ker(B)) = y.$$

We then get a new Matrix $C \in \mathbb{Q}G^{(n+m) \times (n+m)}$ through

$$C = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}.$$

It then holds that

$$\ker(C) \cong \ker(A) \oplus \ker(B)$$

and therefore

$$x + y = \dim_{\mathcal{N}(G)}(\ker(A)) + \dim_{\mathcal{N}(G)}(\ker(B)) = \dim_{\mathcal{N}(G)}(\ker(C))$$

is an ℓ^2 -Betti number arising from G . \square

Lemma 2.3.7. *Let G be a discrete countable group and let H be a discrete finite group. If $x \in \mathbb{R}$ arises from $G \times H$ then $x \cdot |H|$ arises from G .*

To prove this lemma, one can use the fact that if $G_1 \subset G_2$ is a subgroup of finite index $[G_2 : G_1]$, then

$$g_1 = g_2 \cdot [G_2 : G_1]$$

is an ℓ^2 -Betti number arising from G_1 for every ℓ^2 -Betti number g_2 arising from G_2 .¹

3 Turing dynamical systems

To fix notation we will first give a definition of a Turing machine. For convenience we will only allow 1 and 0 as symbols on our tape.

Definition 3.1. A *Turing machine* is a 5-tuple $T = (S, \delta, A, R, I)$ where S is a finite set of states and

$$\delta: \mathbb{Z}/2\mathbb{Z} \times S \setminus (A \cup R) \rightarrow \mathbb{Z}/2\mathbb{Z} \times \{-1, 0, 1\} \times S$$

is called the transition function. $A \subset S$ is called the set of accepting states, $R \subset S$ is called the set of rejecting states and $I \in S$ is called the initial state. A Turing machine is *read-only* if δ fixes the $\mathbb{Z}/2\mathbb{Z}$ -coordinate, i.e.

$$\delta(x, \sigma) = (x, \beta, \tilde{\sigma})$$

for each $x \in \mathbb{Z}/2\mathbb{Z}$ and $\sigma \in S \setminus (A \cup R)$.

In addition each Turing machine uses a “tape”, i.e. a set $\mathbb{Z}/2\mathbb{Z}^{\mathbb{Z}}$ with a “head” on the element corresponding to the index 0. A Turing machine can operate on an element of $Y \in \mathbb{Z}/2\mathbb{Z}^{\mathbb{Z}}$ which is called an input. We start with the initial state and use the transition function δ to get $\delta(Y_0, I)$. The first coordinate corresponds to the new element Y_0 , the third to the new state and the second corresponds to shifting the tape to the left or the right and therefore getting a new Y_0 , e.g. if $\delta(Y_0, I)_3 = 1$ we shift the whole tape one to the left, therefore our new Y_0 is our old Y_1 . We repeat this step until we get a state in $A \cup R$. We say that the Turing machine accepts Y if we get a state in A after finitely many steps and it rejects Y if we get a state in R after finitely many steps. We say that the Turing machine stops for Y if it accepts or rejects it.

For the purpose of calculating ℓ^2 -Betti numbers of groups we need to extend this definition. Let

- (X, μ) be a probability measure space,
- $\bigcup_i X_i$ be a division of X into finitely many disjoint measurable subsets,

¹For a proof of this fact see e.g. [2, p.38].

3 Turing dynamical systems

- Γ be a countable discrete group,
- ρ be a right measure preserving action of Γ on X ,
- A , R and I be three disjoint subsets where each of them is a union of certain X_i . They will be called the accepting set, the rejecting set and the initial set.
- $\gamma_i \in \Gamma$ for each $X_i \subset X$ such that for each i with $X_i \subset A$ or $X_i \subset R$ it holds that $\gamma_i = e$ where e is the neutral element in Γ .

Let $\text{Ind}: X \rightarrow \mathbb{N}$ be the index map, i.e the map for which

$$\text{Ind}(x) = i \Leftrightarrow x \in X_i$$

holds.

Definition 3.2. The map

$$T_X: X \rightarrow X, x \mapsto \rho(\gamma_{\text{Ind}(x)})(x)$$

is called the *Turing map*. The group Γ and the space X (with all the choices of subsets and corresponding γ_i made in the last paragraph) together with the Turing map will be called a *Turing dynamical system* and will be denoted by (T_X) .

Let $x \in X$. If there is a $k \in \mathbb{N}$ such that $T_X^k(x) = T_X^{k+1}(x)$, then it also holds that $T_X^h(x) = T_X^{h+1}(x)$ for all $h \in \mathbb{N}$ with $h \geq k$. We then define $T_X^\infty(x) := T_X^k(x)$. Mostly we don't look at the map T_X but the map T_X^∞ . We say that the Turing dynamical system (T_X) accepts an input $y \in I$ if $T_X^\infty(y) \in A$ and it rejects it if $T_X^\infty(y) \in R$. In addition we say that (T_X) stops for y if it accepts or rejects it.

For every Turing machine there is a Turing dynamical system which does the same as the Turing machine. More precisely for every Turing machine T we can construct a Turing dynamical system (T_X) and a bijection $\Psi: \mathbb{Z}/2\mathbb{Z}^\mathbb{Z} \rightarrow I$ such that T accepts (rejects) an input $Y \in \mathbb{Z}/2\mathbb{Z}^\mathbb{Z}$ if and only if (T_X) accepts (rejects) $\Psi(Y)$. We will use this fact many times in chapter 5. The following example shows how the corresponding Turing dynamical system is constructed. But first let us fix notation.

Notation 3.3. For a set N , let $k, l \in \mathbb{N}$ and $(m_{-k}, \dots, m_l) \in N^{k+l+1}$.

Then let $M \subset N^\mathbb{Z}$ be defined by

$$M := \{(n_i)_{i \in \mathbb{Z}} \in N^\mathbb{Z} \mid n_{-k} = m_{-k}, \dots, n_l = m_l\},$$

i.e. a set where $k + l + 1$ coordinates including the 0-coordinate are fixed. We then simply write $[m_{-k} \cdots \underline{m_0} \cdots m_l]$ for M and $[m_{-k} \cdots \underline{m_0} \cdots m_l][\sigma]$ for $M \times \{\sigma\}$.

Example 3.4. Let $T = (S, \delta, \tilde{A}, \tilde{R}, \tilde{I})$ be a Turing machine. We define $X := \mathbb{Z}/2\mathbb{Z}^\mathbb{Z} \times S$ and $\Gamma := \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z} \times \text{Bij}(S)$. The action of Γ on X is defined by the following rules:

- The generator $\bar{1}$ of the group $\mathbb{Z}/2\mathbb{Z}$ acts on the $\mathbb{Z}/2\mathbb{Z}^\mathbb{Z}$ part of X by adding $\bar{1}$ to the element with index 0.

3 Turing dynamical systems

- The generator 1 of the group \mathbb{Z} acts also on the $\mathbb{Z}/2\mathbb{Z}^{\mathbb{Z}}$ part by shifting every element 1 to the left, i.e. decreasing the index of every element by 1.
- $\text{Bij}(S)$ acts on S in the natural way.

We will now use the transition function to construct the Turing map. We choose the following division of X :

$$X = \bigcup_{x \in \mathbb{Z}/2\mathbb{Z}, \sigma \in S} [\underline{x}][\sigma].$$

For an arbitrary $X_i = [\underline{x}][\sigma]$ we can use the transition function of the Turing machine. Let

$$(\alpha, \beta, \hat{\sigma}) := \delta(x, \sigma) \in \mathbb{Z}/2\mathbb{Z} \times \{-1, 0, 1\} \times S$$

denote the image of (x, σ) .

Now let $\tau \in \text{Bij}(S)$ be some map which sends σ to $\hat{\sigma}$. We can see $x - \alpha \in \mathbb{Z}/2\mathbb{Z}$ as a map on $\mathbb{Z}/2\mathbb{Z}$ which sends x to α . Our element γ_i corresponding to X_i is then given by

$$\gamma_i := \begin{cases} (\bar{0}, 0, \text{id}) & \text{if } X_i \subset A \cup R \\ (x - \alpha, \beta, \tau) & \text{otherwise.} \end{cases}$$

Now we only need to define A , R and I . A is given by

$$A := \bigcup_{x \in \mathbb{Z}/2\mathbb{Z}, \sigma \in \tilde{A}} [\underline{x}][\sigma]$$

which is of course a union of some X_i . R and I can be defined analogously.

The resulting Turing dynamical system (T_X) accepts (rejects) an element in the initial set $Y \times \{\tilde{I}\} \subset I$ if and only if the Turing machine T accepts (rejects) the input $Y \in \mathbb{Z}/2\mathbb{Z}^{\mathbb{Z}}$.

Our ultimate goal is to use Turing dynamical systems to get ℓ^2 -Betti numbers arising from a group. For this purpose some additional definitions and restrictions are needed.

Definition 3.5. The *first fundamental set* $\mathcal{F}_1(T_X)$ is the subset of I consisting of those points x with $T_X^\infty(x) \in A$ such that there is no point y with $T_X(y) = x$. The *second fundamental set* is the subset of A defined as $\mathcal{F}_2(T_X) = T_X^\infty(\mathcal{F}_1(T_X))$. The *first (second) fundamental value* $\Omega_1(T_X)$ ($\Omega_2(T_X)$) is the measure of the corresponding fundamental set.

Definition 3.6. We say that a Turing dynamical system (T_X)

- *stops on any configuration* if $T_X^\infty(x) \in A \cup R$ for almost all $x \in X$,
- *has disjoint accepting chains* if $T_X^\infty(x) \neq T_X^\infty(y)$ for almost all $x, y \in \mathcal{F}_1(T_X)$ with $x \neq y$,

3 Turing dynamical systems

- *does not restart* if the set $T_X(X) \cap I$ has measure 0.

Definition 3.7. Let (T_X) be a Turing dynamical system such that X is an infinite product of $\mathbb{Z}/2\mathbb{Z}$, i.e. X is of the form $\prod_{j \in J} \mathbb{Z}/2\mathbb{Z}$. In addition, X is equipped with the normalized (left) Haar measure and each X_i is of the form

$$X_i = \{(x_j)_{j \in J} \in X \mid x_k = \bar{0} \ \forall k \in I_0, x_h = \bar{1} \ \forall h \in I_1\}.$$

where $I_0, I_1 \subset J$ are finite subsets. If in addition

- the action of Γ is by continuous group automorphisms
- (T_X) stops on any configuration
- (T_X) has disjoint accepting chains
- (T_X) does not restart

(T_X) is called a *computing* Turing dynamical system.

Remark 3.8. For more information on Haar measure see e.g. [5, ch. 2.2]. For us it is only relevant that there always exists a unique normalized (left) Haar measure on G if G is a locally compact Hausdorff topological group.

Note that the (left) Haar measure is left translation invariant.

Lemma 3.9. Let (T_X) be a computing Turing dynamical system with $X = \prod_{j \in J} \mathbb{Z}/2\mathbb{Z}$ and equipped with the normalized Haar measure μ . For a set

$$M = \{(x_j)_{j \in J} \in X \mid x_k = \bar{0} \ \forall k \in I_0, x_h = \bar{1} \ \forall h \in I_1\}$$

with $I_1, I_2 \subset J$ it holds that

$$\mu(M) = \begin{cases} \frac{1}{2^{|I_0|+|I_1|}} & \text{if } I_0 \text{ and } I_1 \text{ are finite} \\ 0 & \text{if } I_0 \text{ or } I_1 \text{ is infinite.} \end{cases}$$

Proof. Let $x \in X$ be an element with $\bar{0}$ on every coordinate $i \notin I_0 \cup I_1$ and $\bar{1}$ on at least one coordinate $i \in I_0 \cup I_1$. Then xM and M are disjoint and because of the left translation invariance of the measure it holds that $\mu(M) = \mu(xM)$. Because for every $i \in I_0 \cup I_1$ we can set the corresponding coordinate either to $\bar{1}$ or to $\bar{0}$ we get $2^{|I_0|+|I_1|}$ of these sets if I_0 and I_1 are finite and an infinite amount of sets if one of them is infinite. The disjoint union of all of these sets is the whole set X so the sum of these measures equals 1 and the claim follows. \square

Before we give an example of a computing Turing dynamical system we fix the notation of the shifting operation, because we will need it later on.

Definition 3.10. An element $z \in \mathbb{Z}$ acts on $\mathbb{Z}/2\mathbb{Z}^{\mathbb{Z}} = \prod_{i \in \mathbb{Z}} \mathbb{Z}/2\mathbb{Z}$ by decreasing every index by z . We call this action the *shift action* and denote it by ζ . \mathbb{Z} acts on $\bigoplus_{i \in \mathbb{Z}} \mathbb{Z}/2\mathbb{Z}$ in the same way and this operation will also be called ζ .

Of course the Turing dynamical system constructed in 3.4 is not computing in most cases. But for many read-only Turing machines a computing Turing dynamical system can be constructed in a similar way.² In fact we will only use read-only Turing machines.

Example 3.11. Let T be a read-only Turing machine, such that the corresponding Turing dynamical system (T_X) as constructed in 3.4 has disjoint accepting chains and stops on any configuration.³

We will construct a computable Turing dynamical system from T . We can easily assure that (T_X) does not restart by adding a new state I' to T with $\delta(x, I') = \delta(x, I)$ for all $x \in \{\bar{0}, \bar{1}\}$ and setting I' as the initial state of T .

Because we do not change the symbols of the tape it suffices to use $\Gamma = \mathbb{Z} \times \text{Bij}(S)$ where \mathbb{Z} operates on the $\mathbb{Z}/2\mathbb{Z}^{\mathbb{Z}}$ part via shifting and $\text{Bij}(S)$ acts on S in the natural way. Because a Turing machine has only finitely many states there exists an integer $n \in \mathbb{N}$ such that $|S| < 2^n$. We identify every state with a different element $z \in \mathbb{Z}/2\mathbb{Z}^n$ with $z \neq 0$.

We can then assume that $X = \mathbb{Z}/2\mathbb{Z}^{\mathbb{Z}} \times \mathbb{Z}/2\mathbb{Z}^n$. We regard every element of $\mathbb{Z}/2\mathbb{Z}^n$, which does not correspond to an actual state, as a “dummy state” which will never be used. Because $\text{Aut}(\mathbb{Z}/2\mathbb{Z}^n)$ acts transitively on all of $\mathbb{Z}/2\mathbb{Z}^n \setminus \{0\}$ we can choose our bijections on S to be group automorphisms. Then $\gamma_i \in \mathbb{Z} \times \text{Aut}(S)$ and therefore we may set $\Gamma := \mathbb{Z} \times \text{Aut}(S)$. It acts on X by continuous group automorphisms.

In this case the sets $X_i = [x][\sigma]$ as constructed in 3.4 have only $n+1$ fixed components, one component to fix x and n components to fix σ . Therefore these sets are of the desired form.

It follows that the resulting Turing dynamical system is computing.

4 Computing ℓ^2 -Betti numbers

In this chapter we want to prove the following central theorem which connects ℓ^2 -Betti numbers to the concept of Turing dynamical systems.

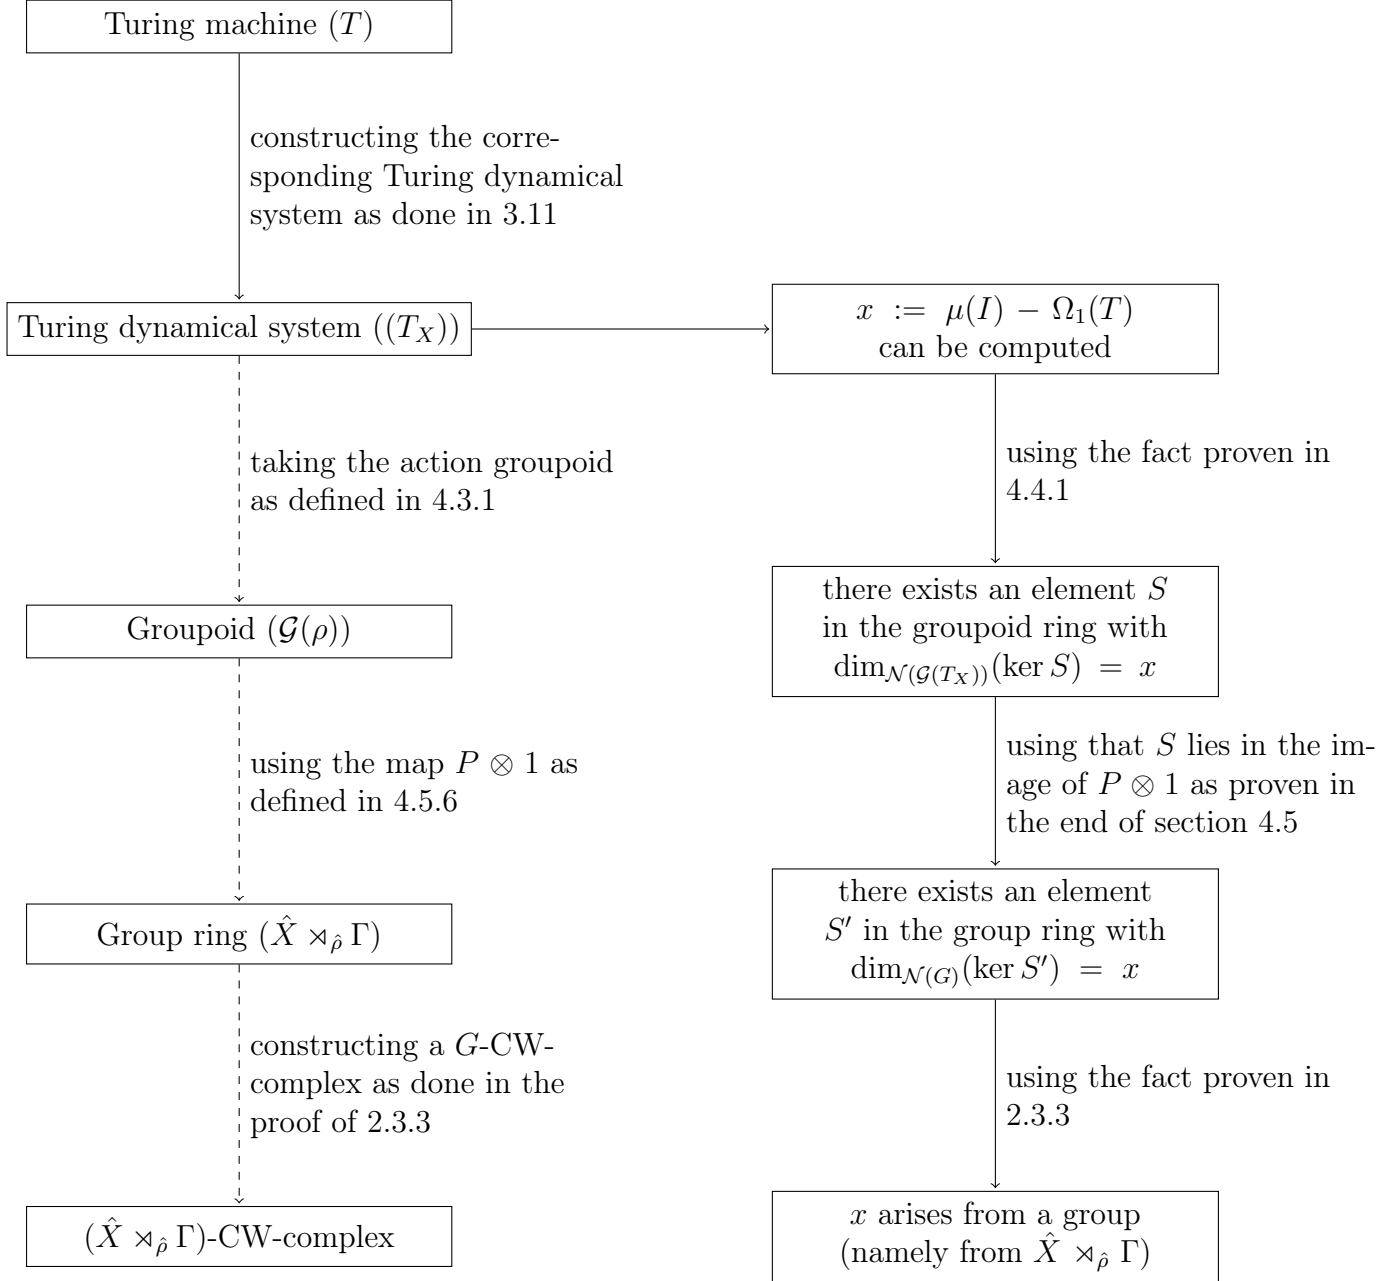

Theorem 4.1. *Let (T_X) be a computing Turing dynamical system. Then $\mu(I) - \Omega_1(T_X)$ is an ℓ^2 -Betti number arising from the group $\hat{X} \rtimes_{\hat{\rho}} \Gamma$ where \hat{X} and $\hat{\rho}$ are the Pontryagin duals of the corresponding group or map.*

We will give the definition of Pontryagin duals and the semidirect product later in this chapter. The rest of this chapter is used to prove this theorem and give the needed definitions.

Figure 3 shows our procedure to prove this Theorem. The main effort will be the proof of Theorem 4.4.1.

²A computable Turing dynamical system can also be constructed for non read-only Turing machines in a different way as in 3.4. The main problem here is that adding $\bar{1}$ to the element of $\mathbb{Z}/2\mathbb{Z}^{\mathbb{Z}}$ with index 0 is not a group-homomorphism.

³This is not the case for all read-only Turing machines.

 Figure 3: Procedure to get an ℓ^2 -Betti number out of a Turing machine.

4.1 Groupoids

We begin by giving some algebraic definitions, namely the construct of groupoids which extends the definition of groups. Therefore we require some basic knowledge about categories.⁴

⁴For more information about category theory see e.g. [6].

Definition 4.1.1. A *groupoid* is a small category whose morphisms are all invertible.

Example 4.1.2. Let G be a group. We want to see how we can express G as a groupoid. Let $\mathcal{G}_0 = \{\bullet\}$ be the set with only one element and \mathcal{G} be the category with objects \mathcal{G}_0 and morphisms $\text{Mor}(\bullet, \bullet) = G$. The composition of morphisms in \mathcal{G} is the same as the multiplication in G . Then \mathcal{G} is a small category and every morphism is invertible because every group element has an inverse. Therefore \mathcal{G} is a groupoid.

We will always denote the set of objects of a groupoid \mathcal{G} by \mathcal{G}_0 and we can identify it with a subset of the set of morphisms of \mathcal{G} by the embedding

$$\mathcal{G}_0 \rightarrow \text{Mor}(\mathcal{G}), X \mapsto [\text{id}: X \rightarrow X]$$

which sends every object to the corresponding identity morphism. Therefore we will only look at $\text{Mor}(\mathcal{G})$ and also call it \mathcal{G} .

We will now give some definitions of basic properties of groupoids which we will use later in this chapter.

Definition 4.1.3. For every groupoid \mathcal{G} we define the maps

$$s: \mathcal{G} \rightarrow \mathcal{G}_0, [f: X \rightarrow Y] \mapsto X$$

and

$$r: \mathcal{G} \rightarrow \mathcal{G}_0, [f: X \rightarrow Y] \mapsto Y$$

which will be called *source* and *range* map.

Definition 4.1.4. A *relation groupoid* is a groupoid with

$$|\text{Mor}(X, Y)| \leq 1 \quad \forall X, Y \in \mathcal{G}_0.$$

Remark 4.1.5. There is a one-to-one correspondence between relation groupoids and equivalence relations.

Definition 4.1.6. If $X \in \mathcal{G}_0$ we denote by $\mathcal{G}X \subset \mathcal{G}_0$ the set of all those objects $Y \in \mathcal{G}_0$ with $\text{Mor}(X, Y) \neq \emptyset$ and call it the *orbit* of X .

Our main use of groupoids will be to construct a groupoid out of a Turing dynamical system (see Figure 3). Therefore we consider groupoids which are also measurable spaces:

Definition 4.1.7. A *discrete measurable groupoid* is a groupoid where \mathcal{G} is also a measurable space, s, r and the maps gained by inverting or composition are all measurable and the fibers of s and r are countable.

If in addition we have a measure μ such that for every $U \subset \mathcal{G}$

$$\int_{\mathcal{G}_0} |r^{-1}(x) \cap U| \, d\mu(x) = \int_{\mathcal{G}_0} |s^{-1}(x) \cap U| \, d\mu(x)$$

holds, we call \mathcal{G} *discrete measured*.

From now on every groupoid will be discrete measured.

Definition 4.1.8. We say that a groupoid \mathcal{G} has *finite orbits* if $\mathcal{G}X$ is finite for almost all $X \in \mathcal{G}_0$.

Definition 4.1.9. Let \mathcal{G} be a relation groupoid with finite orbits. A measurable subset $D \subset \mathcal{G}_0$ such that $|D \cap \mathcal{G}X| = 1$ for every $X \in \mathcal{G}$ with $\mathcal{G}X$ finite is called a *fundamental domain*.

Remark 4.1.10. Up to null-sets a fundamental domain D is an inclusion-minimal subset of \mathcal{G}_0 such that $\mathcal{G}D = \mathcal{G}_0$.

Remark 4.1.11. One can show that every relation groupoid with finite orbits has a fundamental domain.

4.2 Groupoid ring

A fundamental concept used for the calculation of ℓ^2 -Betti numbers of groups was the group ring. We will transfer this to the notion of groupoids.

Definition 4.2.1. Let U be a subset of \mathcal{G}_0 . A *measurable edge* is a map $\Phi: U \rightarrow \mathcal{G}$ such that $s \circ \Phi = \text{id}$ and $r \circ \Phi$ is injective.

From the definition we see, that defining a measurable edge means taking a subset of \mathcal{G}_0 and associating a morphism to every object such that the morphism starts in this object and no two such morphisms end in the same object. We want to define the inverse of a measurable edge in such a way, that it is also a measurable edge. Therefore it does not suffice to take the inverse of the map Φ . Instead we invert each morphism in the image of Φ .

Definition 4.2.2. Let $\Phi: U \rightarrow \mathcal{G}$ be a measurable edge. The *inverse* of Φ will be called Φ^{-1} and is defined as

$$\Phi^{-1}: r(\text{Im}(\Phi)) \rightarrow \mathcal{G}, x \mapsto \Phi(y)^{-1}$$

where y is the unique element in the preimage $(r \circ \Phi)^{-1}(x)$ and $\Phi(y)^{-1}$ is the inverse of the morphism $\Phi(y)$.

One can understand this definition in the following way: If we see a measurable edge as going one step further from every object, then taking the inverse means going one step back. This way of understanding plays a role when we look at groupoids of Turing dynamical systems where taking a measurable edge means applying T_X once.

We now come to the definition of the groupoid ring. We want it to be a ring of operators on $L^2(\mathcal{G})$, such that it is in a way generated by measurable edges.

 Figure 4: Definition of Φ .

 Figure 5: Definition of F .

 Figure 6: Value of $\tilde{\Phi}(F)(x)$.

Definition 4.2.3. For a measurable edge Φ we define an operator $\tilde{\Phi}$ by

$$\tilde{\Phi}: L^2(\mathcal{G}) \rightarrow L^2(\mathcal{G}), F \mapsto \left[\gamma \mapsto \begin{cases} F(\gamma \odot_{\mathcal{G}} \Phi^{-1}(r(\gamma))) & \text{if } r(\gamma) \in \text{Dom}(\Phi^{-1}) \\ 0 & \text{otherwise} \end{cases} \right].$$

In addition for a map $f \in L^\infty(\mathcal{G}_0)$ we also define an operator \tilde{f} on $L^2(\mathcal{G})$ by

$$\tilde{f}: L^2(\mathcal{G}) \rightarrow L^2(\mathcal{G}), F \mapsto [\gamma \mapsto F(\gamma) \cdot f(r(\gamma))].$$

For a groupoid \mathcal{G} the *groupoid ring* $\mathbb{C}\mathcal{G}$ is the ring of bounded operators on $L^2(\mathcal{G})$ generated by all $\tilde{\Phi}$ with Φ measurable edge and all \tilde{f} with $f \in L^\infty(\mathcal{G}_0)$.

Figure 4 to 6 show a simple example of how $\tilde{\Phi}$ can be computed from Φ (every blank black edge in the second and third picture means that the value of this morphism is zero).

4 Computing ℓ^2 -Betti numbers

We always denote the elements of $\mathbb{C}\mathcal{G}$ by a linear combination $\sum_{i \in I} \widetilde{f}_i \odot_{\mathbb{C}\mathcal{G}} \widetilde{\Phi}_i$ (or $\sum_{i \in I} \widetilde{\Phi}_i \odot_{\mathbb{C}\mathcal{G}} \widetilde{f}_i$)⁵ where I is a finite set, Φ_i is a measurable edge and $f_i \in L^\infty(\mathcal{G}_0)$. One can show that each element of $\mathbb{C}\mathcal{G}$ can be represented in such a way. Be aware that this representation is non-unique because there might be several pairs of operators such that their respective compositions are equal. In addition each element in L^∞ can be separated into several elements of L^∞ which sum is equal in the groupoid ring. For example for $f \in L^\infty(\mathcal{G})$ it holds that $\widetilde{\frac{1}{2}f} + \widetilde{\frac{1}{2}f} = \widetilde{f}$.

Example 4.2.4. Let G be a group and \mathcal{G} the corresponding groupoid as in Example 4.1.2. We want to show that the groupoid ring $\mathbb{C}\mathcal{G}$ as a ring is isomorphic to the group ring $\mathbb{C}G$. Because there is only one element in \mathcal{G}_0 the only measurable edges are the maps from $\{\bullet\}$ to G (as a set).

The elements of $L^\infty(\mathcal{G}_0)$ are just maps from $\{\bullet\}$ to \mathbb{C} . Therefore $L^\infty(\mathcal{G}_0)$ is isomorphic to \mathbb{C} .

We now need to show that the composition on $\{\widetilde{\Phi} \mid \Phi \text{ measurable edge}\}$ agrees with the composition on G . On our measurable edges we define the isomorphism: For a measurable edge $\Phi: \bullet \mapsto g$ we map $\widetilde{\Phi}$ to g^{-1} . This map is of course bijective. To see that it is a homomorphism let $\Phi_1: \bullet \mapsto g_1$ and $\Phi_2: \bullet \mapsto g_2$ be measurable edges. It follows that

$$\begin{aligned} & (\widetilde{\Phi}_1 \odot_{\mathbb{C}\mathcal{G}} \widetilde{\Phi}_2)(F)(\gamma) \\ &= (\widetilde{\Phi}_1 \circ \widetilde{\Phi}_2)(F)(\gamma) \\ &= \widetilde{\Phi}_1(\alpha \mapsto F(\alpha \odot_{\mathcal{G}} \Phi_2^{-1}(\bullet)))(\gamma) \\ &= F((\gamma \odot_{\mathcal{G}} \Phi_1^{-1}(\bullet)) \odot_{\mathcal{G}} \Phi_2^{-1}(\bullet)) \\ &= F(\gamma \odot_{\mathcal{G}} g_1^{-1} \odot_{\mathcal{G}} g_2^{-1}) \\ &= F(\gamma \odot_G g_1^{-1} \odot_G g_2^{-1}) \\ &= F(\gamma \odot_G (g_2 \odot_G g_1)^{-1}) \\ &= \widetilde{\Psi}(F)(\gamma) \end{aligned}$$

where Ψ is the measurable edge $\bullet \mapsto g_2 \odot_G g_1$ and is therefore mapped to

$$(g_2 \odot_G g_1)^{-1} = g_1^{-1} \odot_G g_2^{-1}.$$

4.3 Groupoids of Turing dynamical systems

We can now define the action groupoid which will allow us to create a groupoid from a Turing dynamical system.

Definition 4.3.1. Let Γ be a discrete, countable group, X a probability measure space and $\rho: \Gamma \rightarrow \text{Bij}(X)$ a right measure preserving action.

The *action groupoid* $\mathcal{G}(\rho)$ is the groupoid with objects X and morphisms $X \times \Gamma$ such that (x, γ) is a morphism $x \rightarrow \rho(\gamma)(x)$. The composition of morphisms is defined by

$$(x, \gamma_1) \odot_{\mathcal{G}(\rho)} (\rho(\gamma_1)(x), \gamma_2) = (x, \gamma_1 \odot_{\Gamma} \gamma_2).$$

⁵Note that $\mathbb{C}\mathcal{G}$ is not commutative in most cases.

Remark 4.3.2. Let $\mathcal{G}(\rho)$ be an action groupoid of the action $\rho: \Gamma \rightarrow \text{Bij}(X)$. For each element $\gamma \in \Gamma$ we get a measurable edge $\bar{\gamma}: X \rightarrow X \times \Gamma$ which maps $x \in X$ to (x, γ) .

Lemma 4.3.3. If (T_X) is a computing Turing dynamical system with group action ρ , then there is a measure μ on the action groupoid $\mathcal{G}(\rho)$ such that it is a discrete measured groupoid (as defined in Definition 4.1.7) and such that it coincides with the measure on $X = \mathcal{G}(\rho)_0$.

Proof. For a set $U \subset \mathcal{G}(\rho)$ we set

$$\mu'(U) = \int_{\mathcal{G}_0} |s^{-1}(x) \cap U| d\mu(x)$$

where μ is the measure defined on the Turing dynamical system. Then $\mathcal{G}(\rho)$ is of course a discrete measurable groupoid.

To show that it is discrete measured let us first take a set $U \subset \mathcal{G}(\rho)$ of the form

$$U = \{(x, \gamma) \in X \times \Gamma \mid \gamma = \gamma'\}$$

for some $\gamma' \in \Gamma$. Then with the translation invariance of the Haar measure it follows that

$$\begin{aligned} & \int_{\mathcal{G}_0} |s^{-1}(x) \cap U| d\mu(x) \\ &= \int_{\mathcal{G}_0} |s^{-1}(\rho(\gamma')(x)) \cap U| d\mu(\rho(\gamma')(x)) \\ &= \int_{\mathcal{G}_0} |s^{-1}(\rho(\gamma')(x)) \cap U| d\mu(x) \\ &= \int_{\mathcal{G}_0} |r^{-1}(x) \cap U| d\mu(x). \end{aligned}$$

Because each subset of $\mathcal{G}(\rho)$ is a countable disjoint union of such sets the equality holds for all $U \subset \mathcal{G}(\rho)$. \square

From now on for a computing Turing dynamical system with action ρ , $\mathcal{G}(\rho)$ will always be equipped with the measure defined in the proof of 4.3.3.

Definition 4.3.4. Let (T_X) be a computing Turing dynamical system with group action ρ . Then $\mathcal{G}(T_X) \subset \mathcal{G}(\rho)$ is the smallest groupoid with $\mathcal{G}(T_X)_0 = \mathcal{G}(\rho)_0$, which contains all morphisms of the form (x, γ_i) where $i = \text{Ind}(x)$ is the index of the X_i that x is contained in.

Because $\mathcal{G}(T_X)_0 = \mathcal{G}(\rho)_0$, $\mathcal{G}(T_X)$ is still a discrete measured groupoid with the measure inherited from $\mathcal{G}(\rho)$.

Lemma 4.3.5. $\mathcal{G}(T_X)$ is a relation groupoid with finite orbits for every computing Turing dynamical system (T_X) . In addition $A \cup R$ is a fundamental domain of $\mathcal{G}(T_X)$.

4 Computing ℓ^2 -Betti numbers

Proof. First let us have a look at $\mathcal{G}(T_X)$. Its objects are $\mathcal{G}_0 = X$. We then add all morphisms of the form $(x, \gamma_{\text{Ind}(x)})$. We call the subset we have created so far \mathcal{G}' . Of course \mathcal{G}' will usually not be a category. Now we take the smallest groupoid which contains \mathcal{G}' : We add a morphism from x to y for all $x, y \in \mathcal{G}_0$ where there already exists a path of morphisms from x to y in \mathcal{G}' . In addition we add an identity morphism to every $x \in \mathcal{G}_0$ which does not already have one and an inverse morphism to every morphism which does not already have one.

We can then see that we get one morphism from x to y in $\mathcal{G}(T_X)$ for every path of morphisms from x to y in \mathcal{G}' . But x has exactly one outgoing morphism in \mathcal{G}' , therefore $\mathcal{G}(T_X)$ is a relation groupoid.

Because (T_X) stops on any configuration there has to be a path of morphisms in \mathcal{G}' from x to a unique point in $A \cup R$ for almost any $x \in \mathcal{G}(T_X)_0$. Therefore the orbit $\mathcal{G}(T_X)x$ of almost any point $x \in \mathcal{G}(T_X)$ contains exactly one point in $A \cup R$ and $A \cup R$ is a fundamental domain.

To prove that $\mathcal{G}(T_X)$ has finite orbits we restrict the groupoid $\mathcal{G}(T_X)$ to a groupoid $\mathcal{G}(T_X)^\#$ by restricting the objects to those objects x with $\mathcal{G}(T_X)x \cap (A \cup R) \neq \emptyset$. Because (T_X) stops on any configuration, the set of those elements not contained in $\mathcal{G}(T_X)^\#$ has measure 0

For $i \in \mathbb{N}_0$, we define the set $Y_i \subset \mathcal{G}(T_X)_0^\#$ to be the set of points, such that for every point $y \in Y_i$ there is an acyclic path of length i in \mathcal{G}' from y to a point in $A \cup R$, i.e. $T_X^i(y) \in A \cup R$ and $T_X^{i-1} \notin A \cup R$. These sets are disjoint and measurable because T_X is measurable⁶ and therefore $\sum_{i \in \mathbb{N}_0} \mu(Y_i) = 1$. Therefore $\mu(Y_i)$ has to be a zero sequence.

Now consider the set

$$Y := \{y \in A \cup R \mid \mathcal{G}y \text{ is infinite}\}.$$

A Turing dynamical system has only finitely many sets X_i and therefore each point has only finitely many pre-images. Because $T_X^i(Y_i) \subset T_X^{i-1}(Y_{i-1})$ it holds that Y equals $\bigcap_{i \in \mathbb{N}} T_X^i(Y_i)$ and therefore has measure 0. It now holds that

$$\mathcal{G}(T_X)_0^\# = \bigcup_{i \in \mathbb{N}_0} T_X^{-i}(Y) \cup \bigcup_{i \in \mathbb{N}_0} T_x^{-i}((A \cup R) \setminus Y)$$

where $\bigcup_{i \in \mathbb{N}_0} T_X^{-i}(Y)$ contains all infinite orbits and $\bigcup_{i \in \mathbb{N}_0} T_x^{-i}((A \cup R) \setminus Y)$ contains all finite orbits. Because each point has only finitely many pre-images, each of the sets $T_X^{-i}(Y)$ has measure 0 and therefore the countable union $\bigcup_{i \in \mathbb{N}} T_X^{-i}(Y)$ has measure 0. Thus the orbit of almost any point is finite. \square

We are now able to construct a groupoid from a Turing dynamical system. In addition we can construct the corresponding groupoid ring from this groupoid. But we still need a definition a dimension (and therefore some kind of trace) on elements of the groupoid ring (compare Figure 3). Because the concepts are very similar we will also call this dimension the von Neumann dimension (and the von Neumann trace).

⁶This is the case because $T_X|_{X_i} = \rho(\gamma)$, ρ is measure-preserving and there are only finitely many subsets X_i .

4 Computing ℓ^2 -Betti numbers

Definition 4.3.6. Let \mathcal{G} be a groupoid. The *von Neumann trace* of an element $T \in \mathbb{C}\mathcal{G}$ in the groupoid ring is defined by

$$\mathrm{tr}_{\mathcal{N}(\mathcal{G})}(T) = \langle T\chi_0, \chi_0 \rangle_{L^2\mathcal{G}}$$

where χ_0 is the characteristic function of the objects $\mathcal{G}_0 \subset \mathcal{G}$.

Definition 4.3.7. Let \mathcal{G} be a groupoid and $X \subset L^2\mathcal{G}$ be such that there exists a projection $\mathrm{pr}_X: L^2\mathcal{G} \rightarrow X$ with $\mathrm{pr}_X \in \mathbb{C}\mathcal{G}$. The *von Neumann dimension* of X is defined by

$$\dim_{\mathcal{N}(\mathcal{G})}(X) = \mathrm{tr}_{\mathcal{N}(\mathcal{G})}(\mathrm{pr}_X).$$

This definition of a von Neumann dimension is very similar to the one on $\ell^2 G$ given in 2.1.10 when you consider the fact stated in 2.1.11. Again this definition is independent of the chosen projection.

Remark 4.3.8. Let (T_X) be a computing Turing dynamical system with group action ρ . For set $X \subset L^2\mathcal{G}(T_X)$ it holds that

$$\dim_{\mathcal{N}(\mathcal{G}(T_X))}(X) = \dim_{\mathcal{N}(\mathcal{G}(\rho))}(X)$$

because $\mathcal{G}(T_X)_0 = \mathcal{G}(\rho)_0$.

Remark 4.3.9. If $S \in \mathbb{C}\mathcal{G}$ is self-adjoint, then $\ker S$ has a well-defined von Neumann dimension. An argument for this will be given in the proof of 4.5.7.

Remember that for an element $\gamma \in \Gamma$ we can construct a measurable edge $\bar{\gamma}$ of the action groupoid (see 4.3.2) and that for a measurable edge Φ (or a map $f \in L^\infty(\mathcal{G}_0)$) the corresponding element in the groupoid ring is denoted by $\tilde{\Phi}$ (or \tilde{f}) (see 4.2.3).

Lemma 4.3.10. Let $\sum_{i \in I} \tilde{f}_i \tilde{\gamma}_i \in \mathbb{C}\mathcal{G}(\rho)$ with $\rho: \Gamma \rightarrow \mathrm{Bij}(X)$ and $\gamma \in \Gamma$ be an element in the groupoid ring of the action groupoid. Then

$$\mathrm{tr}_{\mathcal{N}(\mathcal{G}(\rho))}\left(\sum_{i \in I} \tilde{f}_i \tilde{\gamma}_i\right) = \sum_{e \in E} \int_{\mathcal{G}(\rho)_0} f_e(x) \, d\mu(x)$$

where E is the set of indices e such that γ_e is the neutral element of Γ . If no such index exists the trace is zero.

Proof. Because $\mathrm{tr}_{\mathcal{N}(\mathcal{G}(\rho))}$ is a homomorphism it is sufficient to show the statement for one summand.

If $\gamma \in \Gamma$ is not the neutral element then the corresponding measurable edge $\bar{\gamma}$ sends every element of $\mathbb{C}\mathcal{G}(\rho)_0$ (i.e. every identity morphism) to a different morphism not contained in $\mathbb{C}\mathcal{G}(\rho)_0$. Therefore for $x \in \mathcal{G}(\rho)_0$ it holds that

$$\tilde{\bar{\gamma}}(\chi_0)(x) = \chi_0(x \odot_{\mathcal{G}(\rho)} \bar{\gamma}(r(x))) = 0$$

4 Computing ℓ^2 -Betti numbers

and thus the trace is 0 for each element if γ is not the neutral element.

Let $e \in \Gamma$ be the neutral element. Then it holds that

$$\begin{aligned}
 & \text{tr}_{\mathcal{N}(\mathcal{G}(\rho))}(\tilde{f}\tilde{e}) \\
 &= \text{tr}_{\mathcal{N}(\mathcal{G}(\rho))}(\tilde{f} \text{id}_{L^2\mathcal{G}}) \\
 &= \langle \tilde{f}(\chi_0), \chi_0 \rangle_{L^2\mathcal{G}(\rho)} \\
 &= \langle \tilde{f}, \chi_0 \rangle_{L^2\mathcal{G}(\rho)_0} \\
 &= \int_{\mathcal{G}(\rho)_0} f(x) \cdot \chi_0(x) \, d\mu(x) \\
 &= \int_{\mathcal{G}(\rho)_0} f(x) \, d\mu(x)
 \end{aligned}$$

which concludes the proof. □

4.4 Construction of an element in the groupoid ring

For an arbitrary computing Turing dynamical system (T_X) we will now construct an element $S \in \mathbb{C}\mathcal{G}(\rho)$ such that $\dim_{\mathcal{N}(\mathcal{G}(T_X))}(\ker S) = \mu(I) - \Omega_1(T_X)$. Because S is a map from $L^2\mathcal{G}(\rho)$ to $L^2\mathcal{G}(\rho)$ it has a kernel which is a subset of $L^2\mathcal{G}(\rho)$ and therefore has a well-defined von Neumann dimension in the sense of 4.3.7.

Theorem 4.4.1. *Let (T_X) be a computing Turing dynamical system with action ρ , division $\bigcup_i X_i$ with associated γ_i and let $\chi_i: \mathcal{G}(T_X) \rightarrow \mathbb{C}$ be the characteristic function of X_i . Then for the element*

$$S = \left(\sum_i \tilde{\gamma}_i \tilde{\chi}_i + \tilde{\chi}_X - \tilde{\chi}_I - \tilde{\chi}_A - \tilde{\chi}_R \right)^* \left(\sum_i \tilde{\gamma}_i \tilde{\chi}_i + \tilde{\chi}_X - \tilde{\chi}_I - \tilde{\chi}_A - \tilde{\chi}_R \right) + \tilde{\chi}_A$$

of the groupoid ring $\mathbb{C}\mathcal{G}(T_X)$ it holds that

$$\dim_{\mathcal{N}(\mathcal{G}(T_X))}(\ker S) = \mu(I) - \Omega_1(T_X).$$

Before we can prove this Theorem we have to do some preparations.

Notation 4.4.2. Let \mathcal{G} be a relation groupoid, $x \in \mathcal{G}_0$ and $R = \sum_{i \in I} \tilde{\Phi}_i \tilde{f}_i \in \mathbb{C}\mathcal{G}$. We then get an operator $R_x: \ell^2\mathcal{G}x \rightarrow \ell^2\mathcal{G}x$ which sends a basis element $1 \cdot y \in \ell^2\mathcal{G}x$ to $\sum_{i \in I'} f_i(y) r(\Phi_i(y))$ where $I' \subset I$ is the set of indices i where y is in the domain of Φ_i .

Remark 4.4.3. *If \mathcal{G} is a relation groupoid with finite orbits then for almost all $x \in \mathcal{G}$ $\ell^2\mathcal{G}x$ is finite dimensional because $\mathcal{G}x$ is finite. In particular in this case R_x has a finite dimensional kernel.*

We will state the following fact without proof. For a proof see [1, ch. 2.6].

Lemma 4.4.4. *Let \mathcal{G} be a relation groupoid with finite orbits and D a fundamental domain of \mathcal{G} . Then for every self-adjoint $R \in \mathbb{C}\mathcal{G}$ it holds that*

$$\dim_{\mathcal{N}(\mathcal{G})}(\ker R) = \int_D \dim(\ker R_x) \, d\mu(x).$$

4 Computing ℓ^2 -Betti numbers

In addition with 4.3.5 we get that for the operator S defined in 4.4.1 it holds that

$$\dim_{\mathcal{N}(\mathcal{G}(T_X))}(\ker S) = \int_{A \cup R} \dim(\ker S_x) d\mu(x)$$

So for a proof it is sufficient to compute the dimension of the kernel of S_x for all $x \in A \cup R$. In addition because T_X is computing it holds that

- $T_X(X) \cap I = \emptyset$, for almost all $x \in X$,
- $T_X^\infty(x) \in A \cup R$ for almost all $x \in X$,
- the orbit $\mathcal{G}(T_X)x$ is finite for almost all $x \in X$.

Because restricting (T_X) to a subset with measure 1 does not change the value of $\int_{A \cup R} \dim(\ker S_x) d\mu(x)$ we can assume that the above statements hold for every $x \in X$ (This is a similar argument as used in the proof of 4.3.5).

Lemma 4.4.5.

$$\ker S_x = \ker\left(\left(\sum_i \widetilde{\gamma}_i \widetilde{\chi}_i\right)_x + \widetilde{\chi}_{X_x} - \widetilde{\chi}_{I_x} - \widetilde{\chi}_{A_x} - \widetilde{\chi}_{R_x}\right) \cap \ker \widetilde{\chi}_{A_x}$$

Proof. First we can see, that for all Operators A on a Hilbert space H it holds that $\ker A = \ker A^*A$. To show this let $x \in \ker A^*A$. It follows that

$$0 = \langle A^*Ax, x \rangle = \langle Ax, Ax \rangle$$

and therefore $x \in \ker A$. The other inclusion is trivial.

From the definition it is clear that $(R_1)_x + (R_2)_x = (R_1 + R_2)_x$ for every $R_1, R_2 \in \mathbb{C}\mathcal{G}$. It remains to show that $R \mapsto R_x$ is $*$ -preserving. Let χ be some characteristic function of a subset of X . Then it follows that both $\widetilde{\chi}$ and $\widetilde{\chi}_x$ are self-adjoint (see the proof of 4.5.6 *iii*) on how to compute the adjoint of an element in the groupoid ring). In addition for an element $\gamma \in \Gamma$ it holds that

$$(\widetilde{\gamma}^*)_x = (\widetilde{\gamma^{-1}})_x = (\widetilde{\gamma}_x)^*.$$

□

Lemma 4.4.6. *It holds that*

$$\dim(\ker S_x) = \begin{cases} |I \cap \mathcal{G}(T_X)x| & \text{if } x \in T_X^\infty(I) \cap R \\ 0 & \text{otherwise} \end{cases}$$

for every $x \in A \cup R$.

4 Computing ℓ^2 -Betti numbers

Proof. First note that because the Turing map T_X maps only finitely many elements onto one element, the set $I \cap \mathcal{G}(T_X)x$ is indeed finite for $x \in T_X^\infty(I) \cap R$.

Let Φ be the measurable edge which sends every object to its identity morphism, i.e. $\Phi = \bar{e}_\Gamma$. For a subset $M \subset X$ it holds that

$$\begin{aligned} & \widetilde{\chi}_{Mx} \\ &= (\widetilde{\Phi} \widetilde{\chi}_M)_x \\ &= [y \mapsto \chi_M(y) \ r(\Phi(y))] \\ &= [y \mapsto \chi_M(y) \ y] \\ &= \left[y \mapsto \begin{cases} y & \text{if } y \in M \\ 0 & \text{otherwise} \end{cases} \right]. \end{aligned}$$

This means that $\widetilde{\chi}_{Mx}$ is a projection onto $\ell^2 M \subset \ell^2 X$.

We can now see that $\widetilde{\chi}_{Xx} - \widetilde{\chi}_{Ix} - \widetilde{\chi}_{Ax} - \widetilde{\chi}_{Rx}$ is zero on $\ell^2(A \cup R \cup I) \cap \ell^2 \mathcal{G}(T_X)x$ and the identity on its complement in $\ell^2 \mathcal{G}(T_X)x$. Now let $x_1 \in I \cap \mathcal{G}(T_X)x$ be one point of $\mathcal{G}(T_X)x$ which is in the initial set. We then get finitely many points $x_1 \dots x_k \in \mathcal{G}(T_X)x$ such that $T_X(x_i) = x_{i+1}$ for every $i \in \{1 \dots k-1\}$ and $x_k = x \in A \cup R$. In addition x_1 is the only one of these points in I . If we regard the points x_i as elements of $\ell^2 \mathcal{G}(T_X)x$ we get that

$$\left(\sum_i \widetilde{\gamma}_i \widetilde{\chi}_i \right)_x (x_i) = \begin{cases} x_{i+1} & \text{if } i < k \\ x_i & \text{if } i = k \end{cases}.$$

Let $P = (\sum_i \widetilde{\gamma}_i \widetilde{\chi}_i)_x + \widetilde{\chi}_{Xx} - \widetilde{\chi}_{Ix} - \widetilde{\chi}_{Ax} - \widetilde{\chi}_{Rx}$. It follows that

$$P(x_i) = \begin{cases} x_{i+1} & \text{if } i = 1 \\ x_i + x_{i+1} & \text{if } i \neq 1, k \\ x_i & \text{if } i = k \end{cases}$$

and therefore

$$P\left(\sum_{i=1}^k (-1)^{i+1} x_i\right) = \sum_{i=2}^k (-1)^{i+1} x_i + \sum_{i=1}^{k-1} (-1)^{i+1} x_{i+1} = 0.$$

It follows that $\sum_{i=1}^k (-1)^{i+1} x_i \in \ker P$ is a non-zero vector in $\ker P$. For each different point $x_1 \in I \cap \mathcal{G}(T_X)x$ we get a new vector $\sum_{i=1}^k (-1)^{i+1} x_i$ in $\ker P$ and all of these vectors are linear independent. Therefore $\dim \ker P \geq |I \cap \mathcal{G}(T_X)x|$.

For the other direction let $x_1 \in \mathcal{G}(T_X)x \setminus I$. Then P maps x_1 to $x_1 + x_2$ (or to x_1 if $x_1 = x$) with $x_2 = T_X(x_1)$. To negate the vector x_2 we have to build a chain of vectors $x_2 \dots x_k$ like we did above. To negate the vector x_1 we need another vector x_0 with $T_X(x_0) = x_1$. But if $x_0 \notin I$ then the vector $-x_0 + x_1$ is mapped to $-x_0 + x_2$. Therefore we have to add another vector x_{-1} with $T_X(x_{-1}) = x_0$. We have to add (subtract) vectors

like this until we add (subtract) a vector x_{-j} with $j \in \mathbb{N}$ such that there is no vector $x_{-(j+1)}$ with $T_X(x_{-(j+1)}) = x_{-j}$. If this vector x_{-j} lies in I , then the constructed chain of vectors lies in the kernel, but is a linear combination of the basis vectors constructed in the last paragraph. In fact there is one of those basis vectors such that it equals this chain (or -1 times this chain). If $x_{-j} \notin I$ then x_{-j} cannot be negated and therefore the constructed chain does not lie in the kernel of P .

In addition it holds that $\widetilde{\chi}_{A_x}$ is the zero map if $x \in R$ and thus $\ker P = \ker S_x$. If $x \in A$ then for each basis vector $\sum_{i=1}^k (-1)^{i+1} x_i$ of $\ker P$ it holds that $x = x_k \notin \ker \widetilde{\chi}_{A_x}$ and $x_1 \dots x_{k-1} \in \ker \widetilde{\chi}_{A_x}$. Therefore $\sum_{i=1}^k (-1)^{i+1} x_i \notin \ker \widetilde{\chi}_{A_x}$ and thus $\ker S_x = \{0\}$. \square

We can now proof Theorem 4.4.1. For convenience we restate the Theorem.

Theorem 4.4.1. *Let (T_X) be a computing Turing dynamical system with action ρ , division $\bigcup_i X_i$ with associated γ_i and let $\chi_i: \mathcal{G}(T_X) \rightarrow \mathbb{C}$ be the characteristic function of X_i . Then for the element*

$$S = \left(\sum_i \widetilde{\gamma}_i \widetilde{\chi}_i + \widetilde{\chi}_X - \widetilde{\chi}_I - \widetilde{\chi}_A - \widetilde{\chi}_R \right)^* \left(\sum_i \widetilde{\gamma}_i \widetilde{\chi}_i + \widetilde{\chi}_X - \widetilde{\chi}_I - \widetilde{\chi}_A - \widetilde{\chi}_R \right) + \widetilde{\chi}_A$$

of the groupoid ring $\mathbb{C}\mathcal{G}(T_X)$ it holds that

$$\dim_{\mathcal{N}(\mathcal{G}(T_X))}(\ker S) = \mu(I) - \Omega_1(T_X).$$

Proof. First note that $\widetilde{\chi}_A$ is self-adjoint (see the proof of 4.5.6 *iii*) on how to compute the adjoint of an element in the groupoid ring) and therefore S is self-adjoint.

Let $U = \{\lambda \in \mathcal{G}(T_X) \mid s(\lambda) \in I, r(\lambda) \in T_X^\infty(I)\}$. We then get

$$\begin{aligned} & \dim_{\mathcal{N}(\mathcal{G}(T_X))}(\ker S) \\ \stackrel{4.4.4}{=} & \int_{A \cup R} \dim(\ker S_x) d\mu(x) \\ \stackrel{4.4.6}{=} & \int_{T_X^\infty(I) \cap R} |I \cap \mathcal{G}(T_X)x| \mu(x) \\ = & \int_{T_X^\infty(I) \setminus A} |I \cap \mathcal{G}(T_X)x| \mu(x) \\ = & \int_{T_X^\infty(I)} |I \cap \mathcal{G}(T_X)x| \mu(x) - \int_{\mathcal{F}_2(T_X)} |I \cap \mathcal{G}(T_X)x| \mu(x) \\ = & \int_{T_X^\infty(I)} |r^{-1}(x) \cap U| \mu(x) - \int_{\mathcal{F}_1(T_X)} 1 \mu(x) \text{ (relation groupoid, disjoint accepting chains)} \\ = & \int_{\mathcal{G}(T_X)_0} |r^{-1}(x) \cap U| \mu(x) - \Omega_1(T_X) \\ = & \int_{\mathcal{G}(T_X)_0} |s^{-1}(x) \cap U| \mu(x) - \Omega_1(T_X) \text{ (discrete measured groupoid (4.1.7))} \\ = & \int_I 1 \mu(x) - \Omega_1(T_X) \\ = & \mu(I) - \Omega_1(T_X) \end{aligned}$$

which concludes the proof. \square

4.5 Pontryagin duality

We will now create a link between the groupoid ring and the group ring. For this we need the Pontryagin duals.

For the rest of this chapter X is a locally compact abelian group, Γ is another group acting on X by continuous group automorphisms. We will call this action $\rho: \Gamma \rightarrow \text{Aut}(X)$.

Definition 4.5.1. A *character* of X is a continuous homomorphism $\hat{x}: X \rightarrow S$, where S is the multiplicative group of complex numbers of absolute value 1. The group of all characters of X is called the *character group* or *Pontryagin dual group* of X and is denoted by \hat{X} .

Remark 4.5.2. It holds that

$$\widehat{\mathbb{Z}/2\mathbb{Z}} \cong \mathbb{Z}/2\mathbb{Z}$$

and

$$\widehat{\prod_{j \in J} X_j} \cong \bigoplus_{j \in J} \hat{X}_j$$

for all compact abelian groups X_j .

For a proof of this statement and for further information on Pontryagin duals see e.g. [5, ch. 4].

Definition 4.5.3. The *Pontryagin dual* $\hat{\rho}: \Gamma \rightarrow \text{Aut}(\hat{X})$ of the action ρ is an action on \hat{X} and defined as

$$\hat{\rho}(\gamma)(f)(x) = f(\rho(\gamma^{-1})(x))$$

for $f \in \hat{X}$ and $x \in X$.

Notation 4.5.4. There is a natural embedding $P: \hat{X} \hookrightarrow L^\infty(X)$.

Definition 4.5.5. Let N, H be groups and $\Theta: H \rightarrow \text{Aut}(N)$ a homomorphism. The *semidirect product* $N \rtimes_\Theta H$ of H and N is defined on the set $N \times H$ with multiplication

$$(n_1, h_1) \odot_{N \rtimes_\Theta H} (n_2, h_2) = (n_1 \odot_N \Theta(h_1)(n_2), h_1 \odot_H h_2).$$

For more information about semidirect products see e.g. [4, ch. IV.5].

We can now define a map from the group ring to the groupoid ring.

Remember that for an element $\gamma \in \Gamma$ we can construct a measurable edge $\bar{\gamma}$ of the action groupoid (see 4.3.2) and that for a measurable edge Φ (or a map $f \in L^\infty(\mathcal{G}_0)$) the corresponding element in the groupoid ring is denoted by $\tilde{\Phi}$ (or f) (see 4.2.3).

Theorem 4.5.6. *The map*

$$P \otimes 1: \mathbb{C}(\hat{X} \rtimes_{\hat{\rho}} \Gamma) \rightarrow \mathbb{C}\mathcal{G}(\rho), \quad \sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot (\hat{x}, \gamma) \mapsto \sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot \widetilde{P(\hat{x})} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{\gamma}$$

with $c_{(\hat{x}, \gamma)} \in \mathbb{C}$ is

- i) a ring-homomorphism
- ii) trace-preserving
- iii) $*$ -preserving

Proof. i) Because of the definition it is clear that $P \otimes 1$ preserves the addition. So let $c_i \in \mathbb{C}$, $\hat{x}_i \in \hat{X}$ and $\gamma_i \in \Gamma$ for $i \in \{1, 2\}$. Then we have

$$\begin{aligned} & P \otimes 1(c_1 \cdot (\hat{x}_1, \gamma_1) \odot_{C(\hat{X} \rtimes_{\hat{\rho}} \Gamma)} c_2 \cdot (\hat{x}_2, \gamma_2)) \\ &= P \otimes 1(c_1 \cdot c_2 \cdot (\hat{x}_1, \gamma_1) \odot_{\hat{X} \rtimes_{\hat{\rho}} \Gamma} (\hat{x}_2, \gamma_2)) \\ &= P \otimes 1(c_1 \cdot c_2 \cdot (\hat{x}_1 \odot_{\hat{X}} \hat{\rho}(\gamma_1)(\hat{x}_2), \gamma_1 \odot_{\Gamma} \gamma_2)) \\ &= c_1 \cdot c_2 \cdot \widetilde{P(\hat{x}_1 \odot_{\hat{X}} \hat{\rho}(\gamma_1)(\hat{x}_2))} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{\gamma_1 \odot_{\Gamma} \gamma_2} \\ &= c_1 \cdot c_2 \cdot \widetilde{P(\hat{x}_1)} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{P(\hat{\rho}(\gamma_1)(\hat{x}_2))} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{\gamma_1} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{\gamma_2}.^7 \end{aligned}$$

Because elements of \mathbb{C} commute with all elements in the groupoid ring it remains to show that

$$\widetilde{P(\hat{\rho}(\gamma_1)(\hat{x}_2))} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{\gamma_1} = \widetilde{\gamma_1} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{P(\hat{x}_2)}.$$

Let $F \in L^2\mathcal{G}(\rho)$ and $\alpha \in \mathcal{G}$. Then

$$\begin{aligned} & \widetilde{P(\hat{\rho}(\gamma_1)(\hat{x}_2))} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{\gamma_1} (F) (\alpha) \\ &= \widetilde{P(\hat{\rho}(\gamma_1)(\hat{x}_2))} (\widetilde{\gamma_1}(F)) (\alpha) \\ &= \widetilde{P(\hat{\rho}(\gamma_1)(\hat{x}_2))} (\beta \mapsto F(\beta \odot_{\mathcal{G}(\rho)} \bar{\gamma}_1^{-1}(r(\beta)))) (\alpha) \\ &= F(\alpha \odot_{\mathcal{G}(\rho)} \bar{\gamma}_1^{-1}(r(\alpha))) \cdot P(\hat{\rho}(\gamma_1)(\hat{x}_2)) (r(\alpha)) \\ &= F(\alpha \odot_{\mathcal{G}(\rho)} \bar{\gamma}_1^{-1}(r(\alpha))) \cdot P(\hat{x}_2 \circ \rho(\gamma_1^{-1})) (r(\alpha)) \\ &= F(\alpha \odot_{\mathcal{G}(\rho)} \bar{\gamma}_1^{-1}(r(\alpha))) \cdot \hat{x}_2 (\rho(\gamma_1^{-1})(r(\alpha))) \\ &= F(\alpha \odot_{\mathcal{G}(\rho)} \bar{\gamma}_1^{-1}(r(\alpha))) \cdot \hat{x}_2 (r(\bar{\gamma}_1^{-1}(r(\alpha)))) \end{aligned}$$

⁷The equality concerning the γ_1, γ_2 -part can be shown in a similar way as in example 4.2.4.

4 Computing ℓ^2 -Betti numbers

and

$$\begin{aligned}
& (\widetilde{\gamma}_1 \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{P(\widehat{x}_2)}) (F) (\alpha) \\
&= (\widetilde{\gamma}_1 \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{\widehat{x}_2}) (F) (\alpha) \\
&= \widetilde{\gamma}_1 (\widetilde{\widehat{x}_2}(F)) (\alpha) \\
&= \widetilde{\gamma}_1 (\beta \mapsto F(\beta) \cdot \widehat{x}_2(r(\beta))) (\alpha) \\
&= F(\alpha \odot_{\mathcal{G}(\rho)} \widetilde{\gamma}_1^{-1}(r(\alpha))) \cdot \widehat{x}_2(r(\alpha \odot_{\mathcal{G}(\rho)} \widetilde{\gamma}_1^{-1}(r(\alpha)))) \\
&= F(\alpha \odot_{\mathcal{G}(\rho)} \widetilde{\gamma}_1^{-1}(r(\alpha))) \cdot \widehat{x}_2(r(\widetilde{\gamma}_1^{-1}(r(\alpha))))
\end{aligned}$$

and those terms are equal.

ii) Let

$$\sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot (\widehat{x}_i, \gamma_i) \in \mathbb{C}(\hat{X} \rtimes_{\hat{\rho}} \Gamma)$$

be an element in the group ring. It then holds that

$$\begin{aligned}
& \text{tr}_{\mathcal{N}(\hat{X} \rtimes_{\hat{\rho}} \Gamma)} \left(\sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot (\widehat{x}_i, \gamma_i) \right) \\
&= \langle \left(\sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot (\widehat{x}_i, \gamma_i) \right) (e_{\hat{X} \rtimes_{\hat{\rho}} \Gamma}), e_{\hat{X} \rtimes_{\hat{\rho}} \Gamma} \rangle \\
&= c_{(e_{\hat{X}}, e_{\Gamma})}.
\end{aligned}$$

We can use 4.3.10 to get

$$\begin{aligned}
& \text{tr}_{\mathcal{N}(\mathcal{G}(\rho))} (P \otimes 1 \left(\sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot (\widehat{x}_i, \gamma_i) \right)) \\
&= \text{tr}_{\mathcal{N}(\mathcal{G}(\rho))} \left(\sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot \widetilde{P(\widehat{x})} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{\gamma} \right) \\
&= \sum_{\hat{x} \in \hat{X}} \int_{\mathcal{G}(\rho)_0} c_{(\hat{x}, e_{\Gamma})} P(\widehat{x})(y) d\mu(y).
\end{aligned}$$

Because $\mu(\mathcal{G}(\rho)_0) = 1$ it follows that

$$\begin{aligned}
& \int_{\mathcal{G}(\rho)_0} c_{(e_{\hat{X}}, e_{\Gamma})} P(e_{\hat{X}})(y) d\mu(y) \\
&= c_{(e_{\hat{X}}, e_{\Gamma})} \cdot \int_{\mathcal{G}(\rho)_0} e_{\hat{X}}(y) d\mu(y) \\
&= c_{(e_{\hat{X}}, e_{\Gamma})} \cdot \int_{\mathcal{G}(\rho)_0} 1 d\mu(y) \\
&= c_{(e_{\hat{X}}, e_{\Gamma})}
\end{aligned}$$

4 Computing ℓ^2 -Betti numbers

and therefore it remains to show that $\int_{\mathcal{G}(\rho)_0} P(\hat{x})(y) d\mu(y) = 0$ if \hat{x} is not the neutral element.

First note that if \hat{x} is not the neutral element then $P(\hat{x})$ is not constant 1 and therefore there exists $z \in \mathcal{G}(\rho)_0$ with $P(\hat{x})(z) \neq 1$. We use the translation invariance of the Haar measure to get

$$\begin{aligned} & \int_{\mathcal{G}(\rho)_0} P(\hat{x})(y) d\mu(y) \\ &= \int_{\mathcal{G}(\rho)_0} P(\hat{x})(z \odot_X y) d\mu(y) \\ &= \int_{\mathcal{G}(\rho)_0} P(\hat{x})(z) P(\hat{x})(y) d\mu(y) \\ &= P(\hat{x})(z) \int_{\mathcal{G}(\rho)_0} P(\hat{x})(y) d\mu(y) \end{aligned}$$

which is only possible if $\int_{\mathcal{G}(\rho)_0} P(\hat{x})(y) d\mu(y) = 0$.

iii) Let us first look at an element of the group ring $cg \in \mathbb{C}G$ of an arbitrary group G . Then for $c_1g_1, c_2g_2 \in \ell^2(G)$ it follows that

$$\begin{aligned} & \langle cg \odot_{\ell^2 G} c_1g_1, c_2g_2 \rangle \\ &= \langle cc_1g \odot_{\ell^2 G} g_1, c_2g_2 \rangle \\ &= \begin{cases} cc_1c_2 & \text{if } gg_1 = g_2 \\ 0 & \text{otherwise} \end{cases} \\ &= \begin{cases} cc_1c_2 & \text{if } g_1 = g^{-1}g_2 \\ 0 & \text{otherwise} \end{cases} \\ &= \langle c_1g_1, cg^{-1} \odot_{\ell^2 G} c_2g_2 \rangle. \end{aligned}$$

Thus the adjoint of cg is cg^{-1} . Analogously the adjoint of an arbitrary element

$$\sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot (\hat{x}, \gamma) \in \mathbb{C}(\hat{X} \rtimes_{\hat{\rho}} \Gamma)$$

is given by

$$\sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot (\hat{x}, \gamma)^{-1} = \sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot (\hat{\rho}(\gamma^{-1})(\hat{x}^{-1}), \gamma^{-1}).$$

Now let $\tilde{\tilde{f}} \in \mathbb{C}\mathcal{G}(\rho)$ be an element of the groupoid ring of an arbitrary action groupoid.

4 Computing ℓ^2 -Betti numbers

Then for $\phi_1, \phi_2 \in L^2\mathcal{G}(\rho)$ it holds that

$$\begin{aligned}
& \langle \tilde{f}\tilde{\gamma}(\phi_1), \phi_2 \rangle_{L^2\mathcal{G}(\rho)} \\
&= \langle \tilde{f}(\beta \mapsto \phi_1(\beta \odot_{\mathcal{G}(\rho)} \bar{\gamma}^{-1}(r(\beta)))) , \phi_2 \rangle_{L^2\mathcal{G}(\rho)} \\
&= \langle \beta \mapsto \phi_1(\beta \odot_{\mathcal{G}(\rho)} \bar{\gamma}^{-1}(r(\beta))) \cdot f(r(\beta)), \phi_2 \rangle_{L^2\mathcal{G}(\rho)} \\
&= \int_{\mathcal{G}(\rho)} \overline{\phi_1(x \odot_{\mathcal{G}(\rho)} \bar{\gamma}^{-1}(r(x))) \cdot f(r(x))} \cdot \phi_2(x) \, d\mu(x) \\
&= \int_{\mathcal{G}(\rho)} \overline{\phi_1(x \odot_{\mathcal{G}(\rho)} \bar{\gamma}(r(x)) \odot_{\mathcal{G}(\rho)} \bar{\gamma}^{-1}(r(x \odot_{\mathcal{G}(\rho)} \bar{\gamma}(r(x)))))) \cdot f(r(x \odot_{\mathcal{G}(\rho)} \bar{\gamma}(r(x))))} \\
&\quad \cdot \phi_2(x \odot_{\mathcal{G}(\rho)} \bar{\gamma}(r(x))) \, d\mu(x) \quad (\text{substituting } x \text{ with } x \odot_{\mathcal{G}(\rho)} \bar{\gamma}(r(x))) \\
&= \int_{\mathcal{G}(\rho)} \overline{\phi_1(x \odot_{\mathcal{G}(\rho)} \bar{\gamma}(r(x)) \odot_{\mathcal{G}(\rho)} \bar{\gamma}^{-1}(r(\bar{\gamma}(r(x)))))) \cdot f(r(\bar{\gamma}(r(x))))} \\
&\quad \cdot \phi_2(x \odot_{\mathcal{G}(\rho)} \bar{\gamma}(r(x))) \, d\mu(x) \\
&= \int_{\mathcal{G}(\rho)} \overline{\phi_1(x) \cdot f(r(\bar{\gamma}(r(x))))} \cdot \phi_2(x \odot_{\mathcal{G}(\rho)} \bar{\gamma}(r(x))) \, d\mu(x) \quad (\text{definition of the inverse 4.2.2}) \\
&= \int_{\mathcal{G}(\rho)} \overline{\phi_1(x) \cdot f(\rho(\gamma)(r(x)))} \cdot \widetilde{\gamma^{-1}(\phi_2)}(x) \, d\mu(x) \\
&= \langle \phi_1, \widetilde{\tilde{f}'\gamma^{-1}(\phi_2)} \rangle_{L^2\mathcal{G}(\rho)}
\end{aligned}$$

with

$$f': X \rightarrow \mathbb{C}, x \mapsto \overline{f(\rho(\gamma)(r(x)))}.$$

Note that for an element $\hat{x} \in \hat{X}$ the inverse is given by

$$\hat{x}^{-1}(y) = \overline{\hat{x}(y)}$$

for all $y \in X$. In this case $\overline{\hat{x}(y)}$ means the complex conjugation of the element $\hat{x}(y)$.

It now holds that

$$\begin{aligned}
 & P \otimes 1 \left(\sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot (\hat{x}, \gamma) \right)^* \\
 &= \left(\sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot \widetilde{P(\hat{x})} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{\gamma} \right)^* \\
 &= \sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot \widetilde{P(\hat{x})'} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{\gamma^{-1}} \\
 &= \sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot \widetilde{P(\hat{\rho}(\gamma^{-1})(\hat{x}^{-1}))} \odot_{\mathbb{C}\mathcal{G}(\rho)} \widetilde{\gamma^{-1}} \\
 &= P \otimes 1 \left(\sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot (\hat{\rho}(\gamma^{-1})(\hat{x}^{-1}), \gamma^{-1}) \right) \\
 &= P \otimes 1 \left(\sum_{(\hat{x}, \gamma) \in \hat{X} \rtimes_{\hat{\rho}} \Gamma} c_{(\hat{x}, \gamma)} \cdot (\hat{x}, \gamma) \right)^*
 \end{aligned}$$

which concludes the proof. \square

Theorem 4.5.7. *Let $R \in \mathbb{C}(\hat{X} \rtimes_{\hat{\rho}} \Gamma)$ be self-adjoint. Then it holds that*

$$\dim_{\mathcal{N}(\hat{X} \rtimes_{\hat{\rho}} \Gamma)}(\ker R) = \dim_{\mathcal{N}(\mathcal{G}(\rho))}(\ker P \otimes 1(R)).$$

Proof. First suppose X and Γ are finite. Therefore $\ell^2(\hat{X} \rtimes_{\hat{\rho}} \Gamma)$ is finite dimensional and R is just a linear map. With the spectral theorem it follows that all eigenvalues of R are real and there exists a basis of eigenvectors. Let $\lambda_1, \lambda_2, \dots, \lambda_n$ denote the distinct non-zero eigenvalues of R . Then

$$Q := \frac{(R - \lambda_1 \text{id}) \circ (R - \lambda_2 \text{id}) \circ \dots \circ (R - \lambda_n \text{id})}{(-1)^n \cdot \lambda_1 \cdot \lambda_2 \cdot \dots \cdot \lambda_n}$$

is a projection onto $\ker R$ and

$$P \otimes 1(Q) = \frac{(P \otimes 1(R) - \lambda_1 \text{id}) \circ (P \otimes 1(R) - \lambda_2 \text{id}) \circ \dots \circ (P \otimes 1(R) - \lambda_n \text{id})}{(-1)^n \cdot \lambda_1 \cdot \lambda_2 \cdot \dots \cdot \lambda_n}.$$

Because $L^2\mathcal{G}(\rho)$ is also finite dimensional and $P \otimes 1(R)$ is still self-adjoint. In addition the spectrum stays the same (because $R|_{\text{Eig}(\lambda_i)} = \lambda_i \text{id}$) and therefore $P \otimes 1(Q)$ is a projection onto $\ker P \otimes 1(R)$. Because $\ker R \subset \ell^2(\hat{X} \rtimes_{\hat{\rho}} \Gamma)$ it follows that

$$\begin{aligned}
 & \dim_{\mathcal{N}(\hat{X} \rtimes_{\hat{\rho}} \Gamma)}(\ker R) \\
 &= \text{tr}_{\mathcal{N}(\hat{X} \rtimes_{\hat{\rho}} \Gamma)}(Q) \\
 &= \text{tr}_{\mathcal{N}(\mathcal{G}(\rho))}(P \otimes 1(Q)) \\
 &= \dim_{\mathcal{N}(\mathcal{G}(\rho))}(\ker P \otimes 1(R)).
 \end{aligned}$$

4 Computing ℓ^2 -Betti numbers

This proves the statement if X and Γ are finite.

If X or Γ are infinite then $\ell^2(\hat{X} \rtimes_{\hat{\rho}} \Gamma)$ is infinite dimensional. Let $l_1 \subset l_2 \subset \dots$ be a series of finite dimensional \mathbb{C} -vector spaces converging to $\ell^2(\hat{X} \rtimes_{\hat{\rho}} \Gamma)$. For each l_i we can restrict R to l_i and the above argument holds. Because $R|_{l_i}$ converges to R the claim follows also for the infinite dimensional case. \square

We now have everything we need to prove Theorem 4.1.

Theorem 4.1. *Let (T_X) be a computing Turing dynamical system. Then $\mu(I) - \Omega_1(T_X)$ is an ℓ^2 -Betti number arising from the group $\hat{X} \rtimes_{\hat{\rho}} \Gamma$ where \hat{X} and $\hat{\rho}$ are the Pontryagin duals of the corresponding group or map.*

Proof. With 4.5.7 it remains to show that the map S from 4.4.1 is contained in $P \otimes 1(\mathbb{Q}(\hat{X} \rtimes_{\hat{\rho}} \Gamma))$ and that there is a self-adjoint pre-image of S in $\mathbb{Q}(\hat{X} \rtimes_{\hat{\rho}} \Gamma)$.⁸

Because our Turing dynamical system is computable, X is an infinite product of $\mathbb{Z}/2\mathbb{Z}$. The group $\widehat{\mathbb{Z}/2\mathbb{Z}}$ consists of only two elements. The neutral element, which maps all of $\mathbb{Z}/2\mathbb{Z}$ to 1 and the element which maps $\bar{0}$ to 1 and $\bar{1}$ to -1 and is therefore isomorphic to $\mathbb{Z}/2\mathbb{Z}$. With the fact stated in 4.5.2 it holds that

$$\begin{aligned} & \hat{X} \\ &= \widehat{\Pi_{j \in J} \mathbb{Z}/2\mathbb{Z}} \\ &\cong \bigoplus_{j \in J} \widehat{\mathbb{Z}/2\mathbb{Z}} \\ &\cong \bigoplus_{j \in J} \mathbb{Z}/2\mathbb{Z}. \end{aligned}$$

Let $g_i \in \hat{X}$ be

$$g_i: X \rightarrow \mathbb{C}, (x_j)_{j \in J} \mapsto \begin{cases} 1 & \text{if } x_i = \bar{0} \\ 0 & \text{if } x_i = \bar{1}. \end{cases}$$

and $e_{\hat{X}} \in \hat{X}$ be the neutral element, i.e. the map which sends every element of X to 1. Let e_{Γ} denote the neutral element of Γ . Then it holds that

$$\begin{aligned} & P \otimes 1 \left(\frac{1}{2}(e_{\hat{X}}, e_{\Gamma}) + \frac{1}{2}(g_i, e_{\Gamma}) \right) \\ &= \frac{1}{2} \widetilde{P(e_{\hat{X}})} + \frac{1}{2} \widetilde{P(g_i)} \\ &= \frac{1}{2} (P(e_{\hat{X}}) + P(g_i)) \\ &= \widetilde{\chi_{Y_i}} \end{aligned}$$

⁸compare 2.3.5

5 The lamplighter group

with

$$Y_i = \{(x_j)_{j \in J} \in X = \mathcal{G}(\rho)_0 \mid x_i = \bar{0}\}.$$

It follows similarly that

$$P \otimes 1(\frac{1}{2}(e_{\hat{X}}, e_{\Gamma}) - \frac{1}{2}(g_i, e_{\Gamma})) = \widetilde{\chi_{Z_i}}$$

with

$$Z_i = \{(x_j)_{j \in J} \in X = \mathcal{G}(\rho)_0 \mid x_i = \bar{1}\}.$$

Therefore all Y_i and Z_i lie in the image $P \otimes 1(\mathbb{Q}(\hat{X} \rtimes_{\hat{\rho}} \Gamma))$.

Let

$$X_i = \{(x_j)_{j \in J} \in X \mid x_k = \bar{0} \ \forall k \in I_0, x_h = \bar{1} \ \forall h \in I_1\}.$$

where $I_0, I_1 \subset J$ are finite subsets, be one of the subsets defined by (T_X) . Then

$$\widetilde{\chi_{X_i}} = \overline{\prod_{k \in I_0} \chi_{Y_k} \cdot \prod_{h \in I_1} \chi_{Z_h}} = \prod_{k \in I_0} \widetilde{\chi_{Y_k}} \odot_{\mathbb{C}\mathcal{G}(\rho)} \prod_{h \in I_1} \widetilde{\chi_{Z_h}}$$

lies in $P \otimes 1(\mathbb{Q}(\hat{X} \rtimes_{\hat{\rho}} \Gamma))$ because $P \otimes 1$ preserves the multiplication.

For a set or an index i let $\xi_i \in \mathbb{Q}(\hat{X} \rtimes_{\hat{\rho}} \Gamma)$ denote a pre-image of $\widetilde{\chi_i}$ under $P \otimes 1$. Because $P \otimes 1$ is a $*$ -preserving ring-homomorphism, a pre-image of S is given by

$$(\sum_i (e_{\hat{X}}, \gamma_i) \xi_i + \xi_X - \xi_I - \xi_A - \xi_R)^* (\sum_i (e_{\hat{X}}, \gamma_i) \xi_i + \xi_X - \xi_I - \xi_A - \xi_R) + \xi_A.$$

Because ξ_A is just a linear combination of elements (\bar{x}, e_{Γ}) the adjoint of ξ_A is given by the same linear combination of the elements $(\bar{x}^{-1}, e_{\Gamma})$ (compare the proof of 4.5.6 *iii*). But each element of $\hat{X} = \widehat{\mathbb{Z}/2\mathbb{Z}} \cong \mathbb{Z}/2\mathbb{Z}$ is self-inverse and therefore ξ_A is self-adjoint. Of course the rest of the pre-image of S is also self-adjoint und thus the claim follows. \square

5 The lamplighter group

5.1 Rational ℓ^2 -Betti numbers

Definition 5.1.1. The *lamplighter group* L is defined as

$$L = (\bigoplus_{i \in \mathbb{Z}} \mathbb{Z}/2\mathbb{Z}) \rtimes_{\zeta} \mathbb{Z}.$$

where ζ is the shift operation defined in 3.10.

Notation 5.1.2. Let G_1, G_2 be groups, X a set and $\rho: G_1 \times G_2 \rightarrow \text{Aut}(X)$ an action of $G_1 \times G_2$ on X . Then there is a natural embedding

$$\iota: G_1 \hookrightarrow G_1 \times G_2, g \mapsto (g, e_{G_2}).$$

By $\rho|_{G_1}: G_1 \rightarrow \text{Aut}(X)$ we denote the action gained through $\rho|_{G_1} = \rho \circ \iota$.

5 The lamplighter group

Let us first look at the Turing dynamical system corresponding to a read-only Turing machine as constructed in 3.11. If we can ensure that the resulting Turing dynamical system has disjoint accepting chains and stops on any configuration we can ensure that it is computing. By using 4.1 we see that $\mu(I) - \Omega_1(T_X)$ is an ℓ^2 -Betti number arising from $\hat{X} \rtimes_{\hat{\rho}} \Gamma$. We then get

$$\begin{aligned} \hat{X} \rtimes_{\hat{\rho}} \Gamma &= \overline{((\prod_{i \in \mathbb{Z}} \mathbb{Z}/2\mathbb{Z}) \times \mathbb{Z}/2\mathbb{Z}^n) \rtimes_{\hat{\rho}} (\mathbb{Z} \times \text{Aut}(\mathbb{Z}/2\mathbb{Z}^n))} \\ &\cong (\bigoplus_{i \in \mathbb{Z}} \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}^n) \rtimes_{\rho} (\mathbb{Z} \times \text{Aut}(\mathbb{Z}/2\mathbb{Z}^n)). \end{aligned}$$

Because \mathbb{Z} acts only on the first factor and $\text{Aut}(\mathbb{Z}/2\mathbb{Z}^n)$ acts only on the second factor of X and \mathbb{Z} acts by shift we get

$$\begin{aligned} \hat{X} \rtimes_{\hat{\rho}} \Gamma &= ((\bigoplus_{i \in \mathbb{Z}} \mathbb{Z}/2\mathbb{Z}) \rtimes_{\zeta} \mathbb{Z}) \times (\mathbb{Z}/2\mathbb{Z}^n \rtimes_{\rho|_{\text{Aut}(\mathbb{Z}/2\mathbb{Z}^n)}} \text{Aut}(\mathbb{Z}/2\mathbb{Z}^n)) \\ &= L \times (\mathbb{Z}/2\mathbb{Z}^n \rtimes_{\rho|_{\text{Aut}(\mathbb{Z}/2\mathbb{Z}^n)}} \text{Aut}(\mathbb{Z}/2\mathbb{Z}^n)). \end{aligned}$$

Therefore we see that read-only Turing machines offer a way to compute the ℓ^2 -Betti number of $L \times H$ for some discrete finite group H . We will use this fact to prove the following theorem.

Theorem 5.1.3. *Every positive rational number arises from the lamplighter group.*

Lets start by constructing an appropriate Turing dynamical system.

Remark 5.1.4. *In this chapter we will often describe Turing machines instead of Turing dynamical systems but because of 3.11 we can always construct the corresponding Turing dynamical system.*

Let us start by considering only a subset of \mathbb{Q} .

Lemma 5.1.5. *For every $m \in \mathbb{N}$ such that $\frac{1}{m}$ has a finite binary expansion there exists a computing Turing dynamical system T_X with*

$$\frac{\Omega_1(T_X)}{\mu(I)} = \frac{1}{m}.$$

Proof. If $m = 1$ we can just construct a Turing machine which accepts every input. So let $m \neq 1$ Let $0.a_1a_2 \dots a_k = \frac{1}{m}$ be the (unique) finite binary expansion of $\frac{1}{m}$. We construct a Turing machine T with $k + 3$ states. These states are

- one accepting and one rejecting state called s_A and s_R
- one initial state called s_I
- k states called s_1, s_2, \dots, s_k .

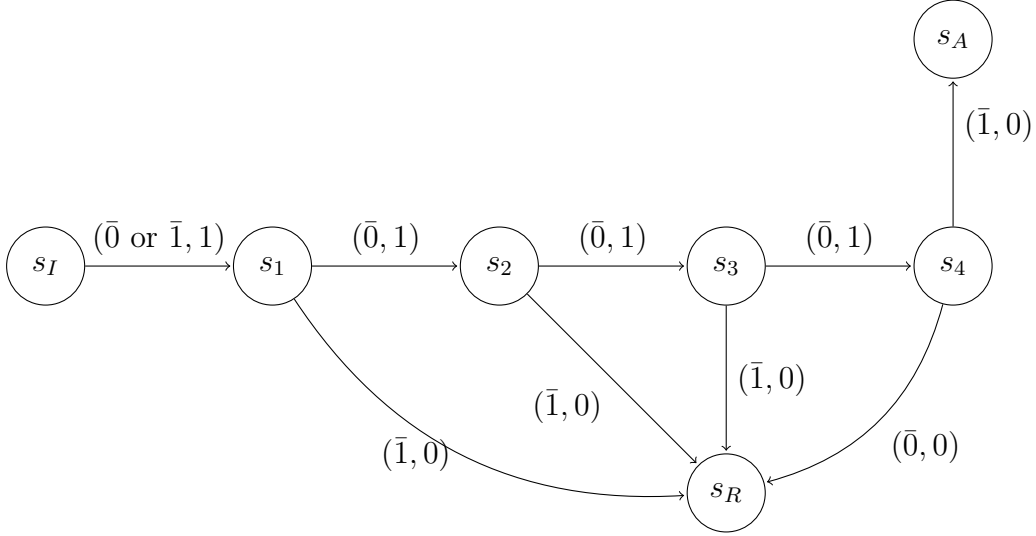

Figure 7: Example of the first Turing machine for the number $\frac{1}{16} = 0.0001$.

The transition function is defined by

$$\begin{aligned} \delta(s_I, x) &= (s_1, x, 1) \quad \forall x \in \mathbb{Z}/2\mathbb{Z} \\ \delta(s_i, \bar{0}) &= \begin{cases} (s_{i+1}, \bar{0}, 1) & \text{if } i \neq k \\ (s_R, \bar{0}, 0) & \text{if } i = k \end{cases} \\ \delta(s_i, \bar{1}) &= \begin{cases} (s_A, \bar{1}, 0) & \text{if } a_i = 1 \\ (s_R, \bar{1}, 0) & \text{if } a_i = 0 \end{cases} \end{aligned}$$

for all $i \in \{1 \dots k\}$. Figure 7 shows an example of this Turing machine for the number $\frac{1}{16} = 0.0001$. In the figure the first number always indicates the number which the Turing machines reads on the tape. The second number refers to shifting the tape, e.g. a 1 on the second coordinate means shifting the tape one to the left.

We now see that the Turing machine stops after at most $k + 2$ steps independent of the current configuration. Therefore the resulting Turing dynamical system (T_X) stops on any configuration. It is also clear that it does not restart.

To ensure that (T_X) has disjoint accepting chains we reduce the initial set I of (T_X) from $[x][s_I]$ to $[\bar{1}][s_I]$ (with $x \in \mathbb{Z}/2\mathbb{Z}$). Because T stops at the first $\bar{1}$ it reads on the right side of its starting point we see that each configuration in the accepting or rejecting set of (T_X) must be contained in

$$[\bar{1} \bar{0}^n \bar{1}][s] \text{ with } s \in \{s_A, s_R\}, n \in \mathbb{N}$$

or

$$[\bar{1} \bar{0}^{k-1} \bar{0}][s_R].$$

5 The lamplighter group

Each of these elements can be traced back to a single element in

$$[\bar{1} \ \bar{0}^n \ \bar{1}][s_I] \text{ or } [\bar{1} \ \bar{0}^k][s_I].$$

Note that we showed an even stronger statement, namely that $T_X^\infty(x) \neq T_X^\infty(y)$ for all $x, y \in I$ with $x \neq y$, not just for almost all in $\mathcal{F}_1(T_X)$. This allows us to exchange s_A with s_R and still be computing.

We claim that for the constructed Turing dynamical system (T_X) it holds that

$$\frac{\Omega_1(T_X)}{\mu(I)} = \frac{1}{m}.$$

Let

$$K = \{i \in \mathbb{N} \mid a_i = 1\}.$$

It then holds that

$$\mathcal{F}_1(T_X) = \bigcup_{i \in K} [\bar{1} \ \bar{0}^{i-1} \bar{1}][s_I].$$

Let $n \in \mathbb{N}$ denote the number such that the space X of (T_X) equals $(\prod_{i \in \mathbb{Z}} \mathbb{Z}/2\mathbb{Z}) \times \mathbb{Z}/2\mathbb{Z}^n$, i.e. the smallest $n \in \mathbb{N}$ such that $k + 3 < 2^n$. Then

$$\mu([\bar{1} \ \bar{0}^{i-1} \bar{1}][s_I]) = \frac{1}{2^{i+1} \cdot 2^n}$$

and

$$\mu(I) = \mu([\bar{1}][s_I]) = \frac{1}{2^{n+1}}.$$

Therefore

$$\frac{\Omega_1(T_X)}{\mu(I)} = \sum_{i \in K} \frac{1}{2^i}$$

which is exactly $\frac{1}{m}$. □

We will now continue by proving the above Lemma for all of \mathbb{Q} .

We will state the following basic fact without proof.

Lemma 5.1.6. *For every $x \in \mathbb{R}$ it holds that $x \in \mathbb{Q}$ if and only if there is a binary expansion of x of the form $\alpha.a\bar{b}$ where α and a are nonrepeating part, b is a repeating part and the lengths of α, a and b are all finite.*

Lemma 5.1.7. *For every $m \in \mathbb{N}$ there exists a computing Turing dynamical system T_X with*

$$\frac{\Omega_1(T_X)}{\mu(I)} = \frac{1}{m}.$$

Figure 8: Example of the second Turing machine for a number $\frac{1}{6} = 0.00\overline{1}$.

Proof. Without loss of generality $m \neq 1$. Then 5.1.6 provides a binary expansion

$$\frac{1}{m} = 0.a_1a_2\dots a_k\overline{b_1b_2\dots b_h}$$

where $a_1a_2\dots a_k$ is nonrepeating and $b_1b_2\dots b_h$ is repeating. We then construct the same Turing machine as in 5.1.5 but add h many states called $r_1, r_2\dots r_h$. Instead of $\delta(s_k, \bar{0}) = (s_R, \bar{0}, 0)$ we set $\delta(s_k, \bar{0}) = (r_1, \bar{0}, 1)$ and

$$\delta(r_i, \bar{0}) = \begin{cases} (r_{i+1}, \bar{0}, 1) & \text{if } i \neq h \\ (r_1, \bar{0}, 1) & \text{if } i = h \end{cases}$$

$$\delta(r_i, \bar{1}) = \begin{cases} (s_A, \bar{1}, 0) & \text{if } b_i = 1 \\ (s_R, \bar{1}, 0) & \text{if } b_i = 0 \end{cases}$$

which takes care of the repeating part of $\frac{1}{m}$. The rest of the transition function δ stays the same as in 5.1.5. Figure 8 shows an example of this Turing machine for the number $\frac{1}{6} = 0.00\overline{1}$.

We can see that this Turing machine does not stop for every input, because if we have only zeros on the right side of our starting point, we never arrive at s_A or s_R . But because the set $[x \ 0 \ 0 \dots][\sigma]$ (with $x \in \mathbb{Z}/2\mathbb{Z}$ and σ an arbitrary state) has measure zero the resulting Turing dynamical system still stops on any configuration. The rest follows exactly like in the proof of 5.1.5 because the infinite sum of measures converges. \square

We can now start to prove 5.1.3.

Theorem 5.1.3. *Every positive rational number arises from the lamplighter group.*

5 The lamplighter group

Proof. Because of the additivity of numbers arising from a group proven in 2.3.6 it suffices to show that for every $m \in \mathbb{N}$, $\frac{1}{m}$ arises from L . Let $m \in \mathbb{N}$ and (T_X) be the Turing dynamical system constructed in the proof of 5.1.7. First we see that

$$\begin{aligned} & \mu(I) - \Omega_1(X) \\ &= \mu(I) \left(1 - \frac{\Omega_1(T_X)}{\mu(I)}\right) \text{ (note that } \mu(I) \neq 0) \\ &= \mu(I) \left(1 - \frac{1}{m}\right) \end{aligned}$$

is an ℓ^2 -Betti number of

$$L \times (\mathbb{Z}/2\mathbb{Z}^n \rtimes_{\rho|_{\text{Aut}(\mathbb{Z}/2\mathbb{Z}^n)}} \text{Aut}(\mathbb{Z}/2\mathbb{Z}^n))$$

for some $n \in \mathbb{N}$.

Let k denote the number of states of the Turing machine T constructed in 5.1.7 and $k' \in \mathbb{N}$ be such that $k < k'$ and $k' = 2^h$ for some $h \in \mathbb{N}$. We now change (T_X) by adding “dummy states” until (T_X) has $2^{k'}$ many states. Doing so does not change the value of $\frac{\Omega_1(T_X)}{\mu(I)}$. We now construct the corresponding Turing dynamical system $(T_{X'})$ in the same way as in example 3.11 but we set $X' = \mathbb{Z}/2\mathbb{Z}^{\mathbb{Z}} \times \mathbb{Z}/2\mathbb{Z}^{k'}$ and identify every state of T with an element of the standard basis of $\mathbb{Z}/2\mathbb{Z}^{k'}$. In addition we set $\Gamma = \mathbb{Z} \times \text{Rot}$ where Rot is the subgroup of $\text{Aut}(\mathbb{Z}/2\mathbb{Z}^{k'})$ generated by the automorphism which rotates every element one to the right, i.e.

$$\phi: \mathbb{Z}/2\mathbb{Z}^{k'} \rightarrow \mathbb{Z}/2\mathbb{Z}^{k'}, \sum_{i=1}^{k'} z_i \cdot e_i \mapsto \sum_{i=2}^{k'} z_{i-1} \cdot e_i + z_{k'} \cdot e_1$$

where e_i denotes the standard basis of $\mathbb{Z}/2\mathbb{Z}^{k'}$ and each $z_i \in \mathbb{Z}/2\mathbb{Z}$. Then Rot acts transitively on the standard basis of $\mathbb{Z}/2\mathbb{Z}^{k'}$ and has exactly $k' = 2^h$ elements.

Then

$$\frac{1}{2^{k'+1}} \left(1 - \frac{1}{m}\right)$$

is an ℓ^2 -Betti number of $L \times (\mathbb{Z}/2\mathbb{Z}^{k'} \rtimes_{\rho|_{\text{Rot}}} \text{Rot})$. With the multiplicativity stated in 2.3.7 it follows that

$$\begin{aligned} & |(\mathbb{Z}/2\mathbb{Z}^{k'} \rtimes_{\rho|_{\text{Rot}}} \text{Rot})| \cdot \frac{1}{2^{k'+1}} \left(1 - \frac{1}{m}\right) \\ &= 2^{k'} \cdot 2^h \cdot \frac{1}{2^{k'+1}} \left(1 - \frac{1}{m}\right) \\ &= 2^{h-1} \left(1 - \frac{1}{m}\right) \end{aligned}$$

is an ℓ^2 -Betti number arising from L . We reduce $\mu(I)$ by changing I to

$$[\bar{1}^{h-1} \bar{1}][s_I]$$

and we get that $(1 - \frac{1}{m})$ is a ℓ^2 -Betti number arising from L . At last by interchanging s_A and s_R we get that $\frac{1}{m}$ is a ℓ^2 -Betti number of L which concludes the proof. \square

5.2 Irrational ℓ^2 -Betti numbers

We have seen in the last section that every rational number arises from the lamplighter group. We will now show that in addition there are also irrational numbers which arise from L^3 . To be more precise, we show that a specific irrational number arises from L^3 .

Remark 5.2.1. *The definition of a Turing machine can easily be expanded to a Turing machine with multiple tapes, i.e. a Turing machine which acts on $(\mathbb{Z}/2\mathbb{Z}^k)^\mathbb{Z}$ for $k \in \mathbb{N}$ instead of just $\mathbb{Z}/2\mathbb{Z}^\mathbb{Z}$. In this case we get a transition function*

$$\delta: S \setminus (A \cup R) \times \mathbb{Z}/2\mathbb{Z}^k \rightarrow S \times \mathbb{Z}/2\mathbb{Z}^k \times \{-1, 0, 1\}^k.$$

Notation 5.2.2. Similar to the notation introduced in 3.3 we introduce a notation for a Turing machine on 3 tapes:

Let T be a Turing machine on 3 tapes. For a subset $M \times S \subset X$ of the corresponding Turing dynamical system (T_X) with

$$M = \{(a_i, b_i, c_i)_{i \in \mathbb{Z}} \in (\mathbb{Z}/2\mathbb{Z}^3)^\mathbb{Z} \mid a_{-\alpha} = l_{-\alpha}, \dots, a_\beta = l_\beta, \\ b_{-\gamma} = m_{-\gamma}, \dots, b_\delta = m_\delta, c_{-\epsilon} = n_{-\epsilon}, \dots, c_\zeta = n_\zeta\}$$

with $\alpha, \beta, \gamma, \delta, \epsilon, \zeta \in \mathbb{N}$ we simply write

$$\begin{bmatrix} l_{-\alpha} \cdots \underline{l_0} \cdots l_\beta \\ m_{-\gamma} \cdots \underline{m_0} \cdots m_\delta \\ n_{-\epsilon} \cdots \underline{n_0} \cdots n_\zeta \end{bmatrix}.$$

Similarly we write

$$\begin{bmatrix} l_{-\alpha} \cdots \underline{l_0} \cdots l_\beta \\ m_{-\gamma} \cdots \underline{m_0} \cdots m_\delta \\ n_{-\epsilon} \cdots \underline{n_0} \cdots n_\zeta \end{bmatrix} [\sigma]$$

for the subset $M \times \{\sigma\} \subset X$.

Theorem 5.2.3. *The number*

$$\frac{1}{64} - \frac{1}{8} \sum_{i=1}^{\infty} \frac{1}{2^{i^2+3i+6}}$$

arises from L^3 .

Proof. To prove this fact we will first construct a read-only Turing machine T on 3 tapes with 6 states. These states are

- one accepting and one rejecting state called s_A and s_R
- one initial state called s_I
- 3 states called s_1, s_2 and s_3 .

Figure 9: Transition function of the third Turing machine (The rejecting state is omitted).

The transition function is defined by

$$\begin{aligned}
 \delta(s_I, (x_1, x_2, x_3)) &= \begin{cases} (s_1, (x_1, x_2, x_3), (1, 1, 0)) & \text{if } x_1 = x_2 = x_3 = \bar{1} \\ (s_R, (x_1, x_2, x_3), (0, 0, 0)) & \text{otherwise} \end{cases} \\
 \delta(s_1, (x_1, x_2, x_3)) &= \begin{cases} (s_1, (x_1, x_2, x_3), (1, 1, 0)) & \text{if } x_1 = x_2 = \bar{0} \text{ and } x_3 = \bar{1} \\ (s_2, (x_1, x_2, x_3), (-1, -1, 1)) & \text{if } x_1 = x_2 = x_3 = \bar{1} \\ (s_R, (x_1, x_2, x_3), (0, 0, 0)) & \text{otherwise} \end{cases} \\
 \delta(s_2, (x_1, x_2, x_3)) &= \begin{cases} (s_2, (x_1, x_2, x_3), (-1, 0, 0)) & \text{if } x_1 = x_2 = x_3 = \bar{0} \\ (s_3, (x_1, x_2, x_3), (1, 0, 0)) & \text{if } x_1 = \bar{1} \text{ and } x_2 = x_3 = \bar{0} \\ (s_A, (x_1, x_2, x_3), (0, 0, 0)) & \text{if } x_1 = \bar{0} \text{ and } x_2 = x_3 = \bar{1} \\ (s_R, (x_1, x_2, x_3), (0, 0, 0)) & \text{otherwise} \end{cases} \\

 \end{aligned}$$

Figure 9 shows the transition function in the same way as in Figure 7. In Figure 9 the rejecting state is omitted. Instead we go to the rejecting state when we encounter a tape configuration not explicitly noted.

Figure 10 shows an example of the workflow of this Turing machine. The rightmost column shows the current state, the other rows show a part of the content of the 3 tapes. The current position of the head (i.e. the element at the position with index 0) is painted gray.

[illegible]

Figure 10: An example of the workflow of the third Turing machine.

5 The lamplighter group

Of course we will again look at the corresponding Turing dynamical system (T_X) where we will set

$$I = \begin{bmatrix} \bar{1} \\ \bar{1} \\ \bar{1} \end{bmatrix} [s_I].$$

Now let us look at T and figure out which input is accepted by T . Because of our definition of I we can suppose that each of our tapes has a $\bar{1}$ at the zero-position at the beginning. So it is clear that we are at the state s_1 after one step with a secure $\bar{1}$ at the third tape. If we have $\bar{0}$ on our first two tapes we remain at s_1 and if we have $\bar{1}$ on our first two tapes we get to s_2 . Therefore to get to s_2 our input has to be of the form

$$\begin{bmatrix} \bar{1}\bar{0}^j\bar{1} \\ \bar{1}\bar{0}^j\bar{1} \\ \bar{1} \end{bmatrix}$$

with $j \in \mathbb{N}$. After several applications of (T_X) we reach s_2 for the first time and get a configuration of the form

$$\begin{bmatrix} \bar{1}\bar{0}^{j-1}\bar{0}\bar{1} \\ \bar{1}\bar{0}^{j-1}\bar{0}\bar{1} \\ \bar{1}\underline{x} \end{bmatrix} [s_2].$$

with $x \in \mathbb{Z}/2\mathbb{Z}$.

When we are at state s_2 we shift our first tape backward until we reach our first $\bar{1}$. We then go to s_3 and shift our first and third tape forward until we reach our second $\bar{1}$ on the first tape, i.e. we do j -many shifts on the third tape. We then shift our second tape one position backward and repeat this whole process because we are again at state s_2 . We do this until we get back to the $\bar{1}$ on our second tape. If this is the first time we see a $\bar{1}$ on our third tape we accept. In every other case we reject.

Therefore in order to accept we need to have $j \cdot (j+1) = j^2 + j$ many $\bar{0}$ on the third tape. Therefore it holds that

$$\mathcal{F}_1(T_X) = \bigcup_{j \in \mathbb{N}} \begin{bmatrix} \bar{1}\bar{0}^j\bar{1} \\ \bar{1}\bar{0}^j\bar{1} \\ \bar{1}\bar{0}^{j^2+j}\bar{1} \end{bmatrix} [s_I].$$

Because our Turing dynamical system has 8 states this set has measure

$$\Omega_1(T_X) = \mu(\mathcal{F}_1(T_X)) = \frac{1}{8} \sum_{j=1}^{\infty} \frac{1}{2^{j^2+3j+6}}.$$

In addition it holds that $\mu(I) = \frac{1}{64}$ and therefore

$$\mu(I) - \Omega_1(T_X) = \frac{1}{64} - \frac{1}{8} \sum_{j=1}^{\infty} \frac{1}{2^{j^2+3j+6}}.$$

It remains to show that (T_X) is computable, which means that we have to show that

5 The lamplighter group

- the set $\{x \in X \mid T_X^\infty(x) \notin A \cup R\}$ has measure 0
- $T_X(X) \cap I$ has measure 0
- $T_X^\infty(x) \neq T_X^\infty(y)$ for almost all $x, y \in \mathcal{F}_1(T_X)$ with $x \neq y$.

First let us look at the set

$$\{x \in X \mid T_X^\infty(x) \notin A \cup R\}.$$

We will show that this set is contained in

$$\bigcup_{x,y,z \in \mathbb{Z}/2\mathbb{Z}} \begin{bmatrix} \underline{x}\bar{0}^\infty \\ \underline{y}\bar{0}^\infty \\ \underline{z} \end{bmatrix} \cup \begin{bmatrix} \underline{x} \\ \underline{y} \\ \underline{z}\bar{0}^\infty \end{bmatrix}.$$

There are only two ways to get into an infinite loop. We can remain indefinitely at s_1 if we do not find any $\bar{1}$ on the right side of one of the first two tapes. The second possibility is that we remain forever in s_2 and s_3 . But as we can see from the transition function this is only possible if we do not find any $\bar{1}$ on the right side of the third tape. So we see the above inclusion and because each of the sets of the union has measure zero and thus (T_X) stops on any configuration.

Because there is no way to get back to s_I , $T_X(X) \cap I = \emptyset$ and therefore (T_X) does not restart.

In addition each element x of the set A is contained in some set of the form

$$\begin{bmatrix} \bar{1}\bar{0}^{j-1}\bar{0}\bar{1} \\ \bar{1}\bar{0}^j\bar{1} \\ \bar{1}\bar{0}^{j^2+j}\bar{1} \end{bmatrix} [s_A]$$

which can be traced back to a unique element of

$$\begin{bmatrix} \bar{1}\bar{0}^j\bar{1} \\ \bar{1}\bar{0}^j\bar{1} \\ \bar{1}\bar{0}^{j^2+j}\bar{1} \end{bmatrix} [s_I].$$

Therefore (T_X) has disjoint accepting chains and the claim follows. \square

It is easy to see that

$$x := \frac{1}{64} - \frac{1}{8} \sum_{i=1}^{\infty} \frac{1}{2^{i^2+3i+6}}$$

is in fact irrational: Let us look at the binary expansion of x . Because of the i^2 -part in the sum the distance between two consequent 1 gets bigger at the latter part of this expansion. Therefore the binary expansion of x cannot be of the form mentioned in 5.1.6 and is therefore irrational.

This shows that an irrational number can in fact be an ℓ^2 -Betti number arising from a group which disproves the strong Atiyah conjecture.
